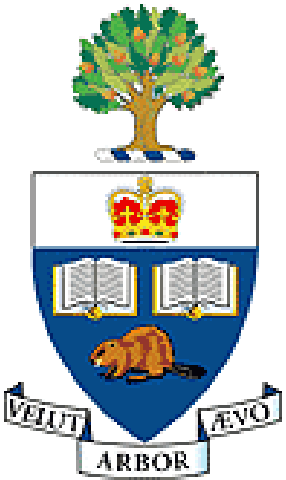
An 18-Gene Signature Predicting Treatment Response to Interferon in Patients Chronically Infected with Hepatitis C Virus

Dr. Limin Chen

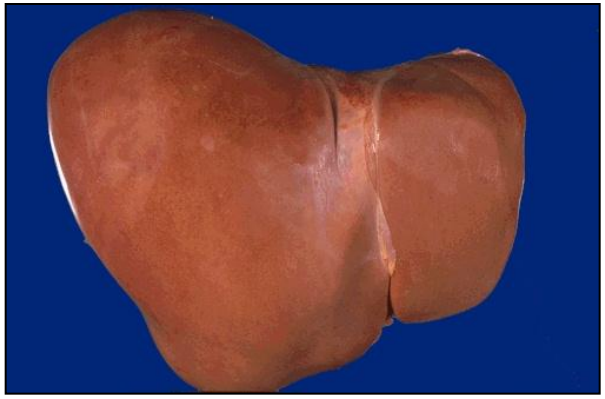
Institute of Blood Transfusion, Chinese Academy of Medical Sciences/Peking Union Medical College, China &

University of Toronto, Canada



HCV infection: a serious liver disease

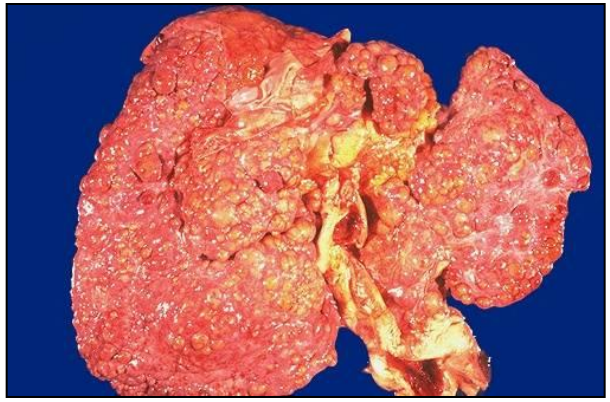
Normal liver



HCV

PegIFN/Rib

Cirrhosis & HCC



Predict treatment response
Mechanism of IFN resistance

50% effective

50% failure

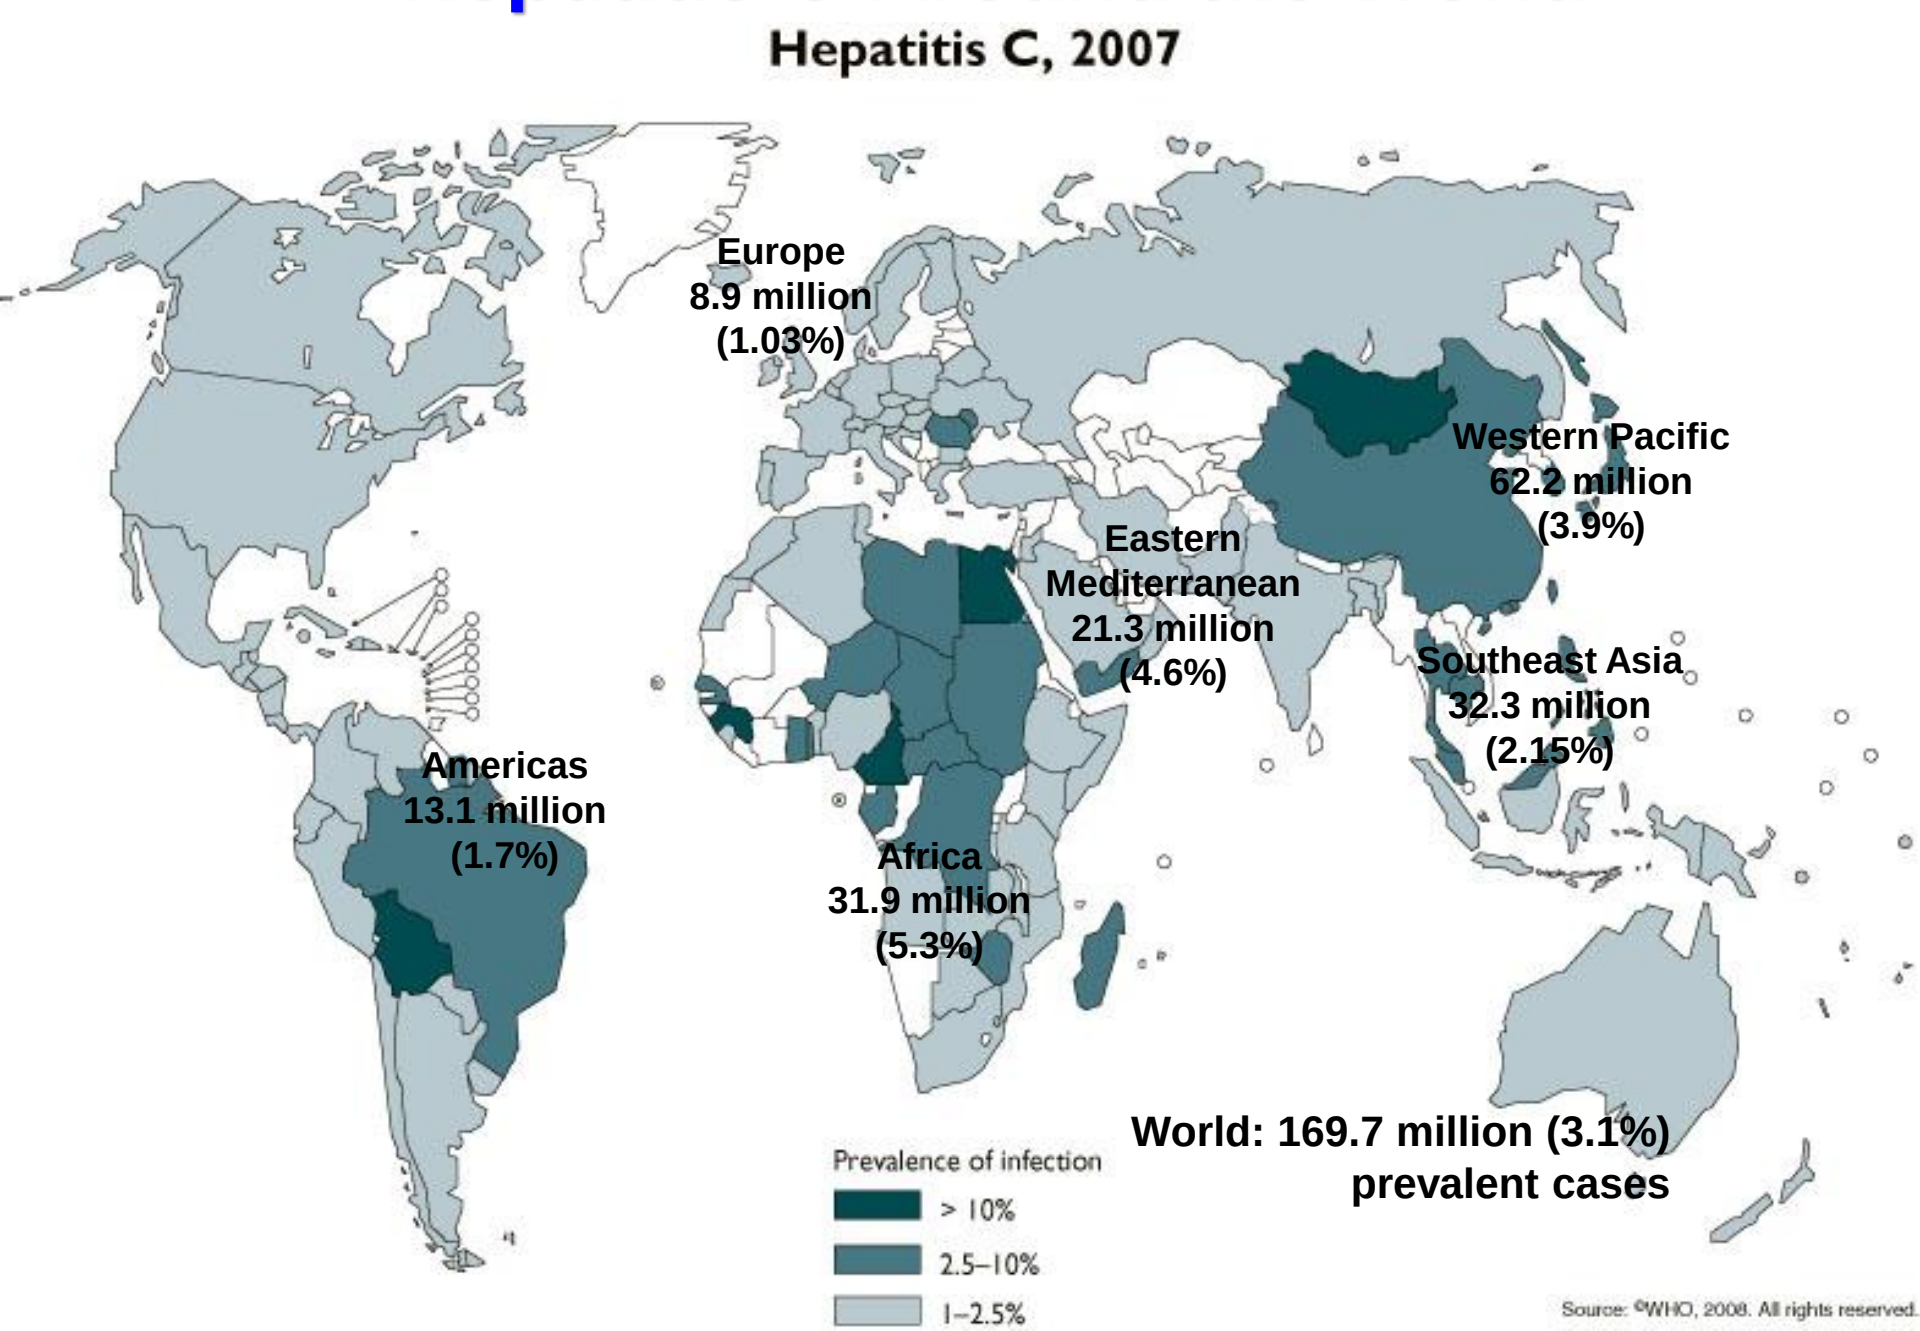
Presentation outline

- **Introduction to HCV:** -milestones in HCV research
  -diagnosis and treatment

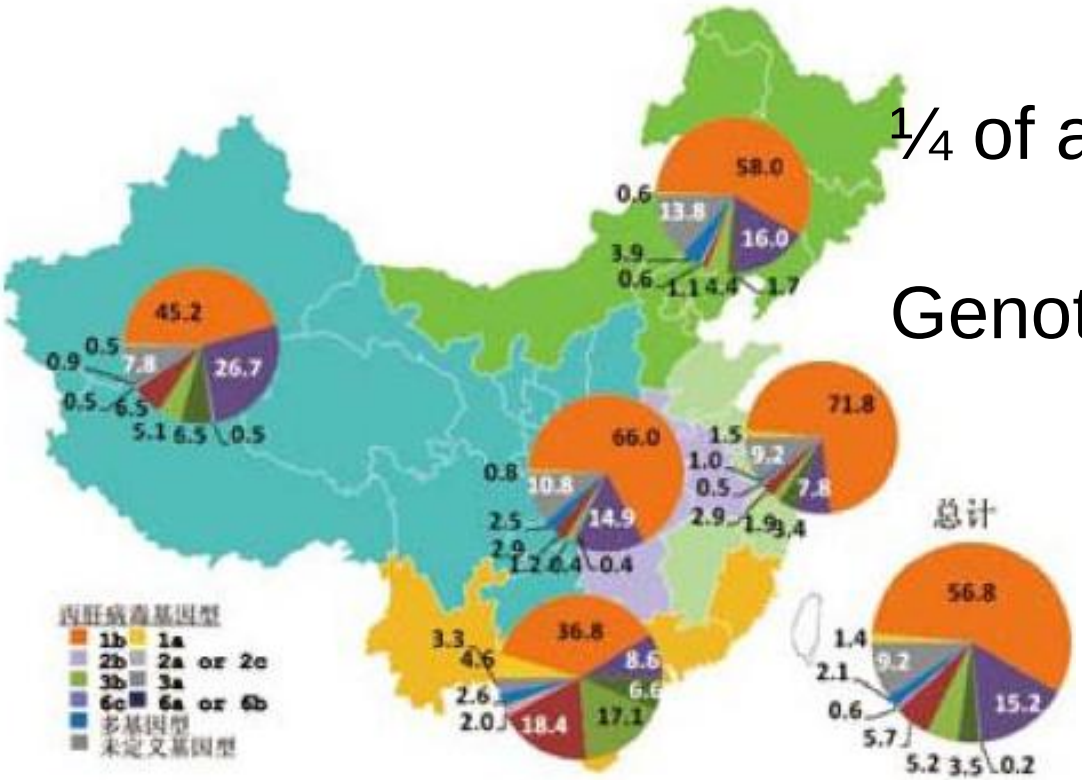
- **Identification of HCV response signature** by microarray gene expression profiling

Part I: Introduction to HCV infection

Hepatitis C Around the World



HCV in China

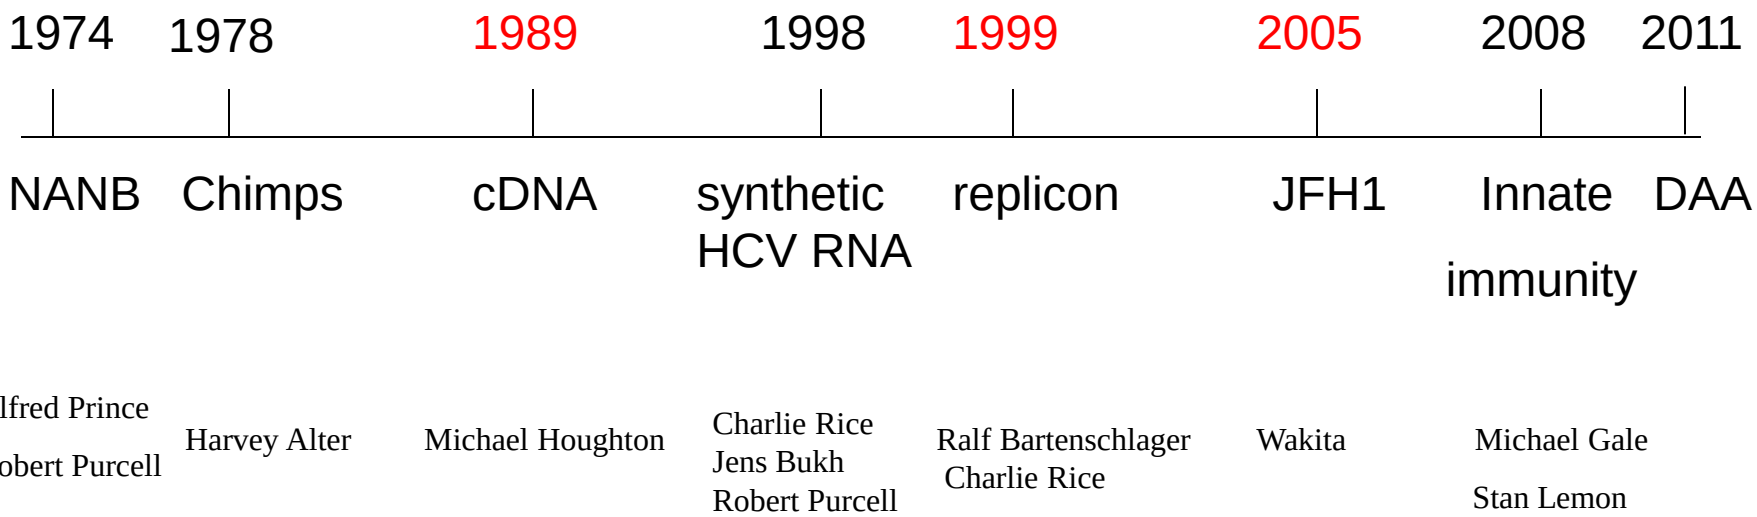


40 million people infected

¼ of all infected worldwide

Genotype 1b most common

Milestones for HCV research



Michael Houghton and Harvey Alter (Lasker Award 2002)

Isolated Filtratable Agent and Sequenced Genome of Hepatitis C Virus

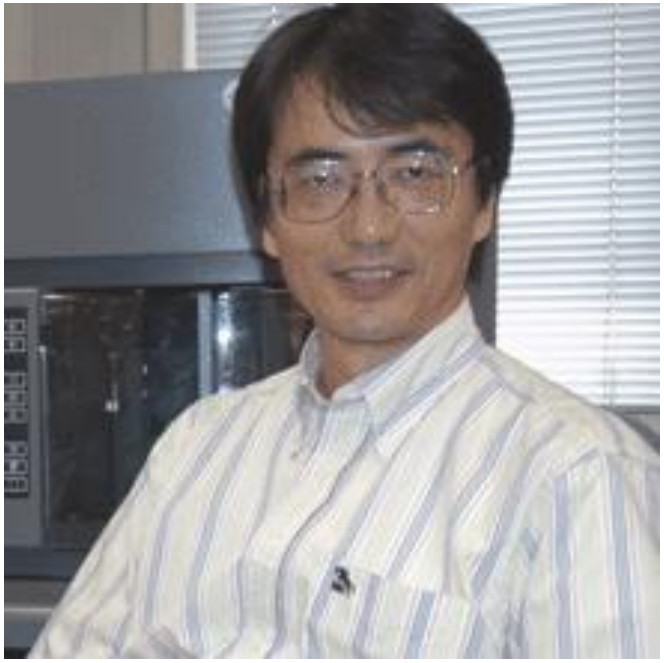
Charlie Rice (Rockefeller University)

Injected synthetic HCV RNA genome into chimps to cause hepatitis C (1998)

Ralf Bartenschlager (left) Developed Replicon System

Allows HCV RNA replication in cell culture

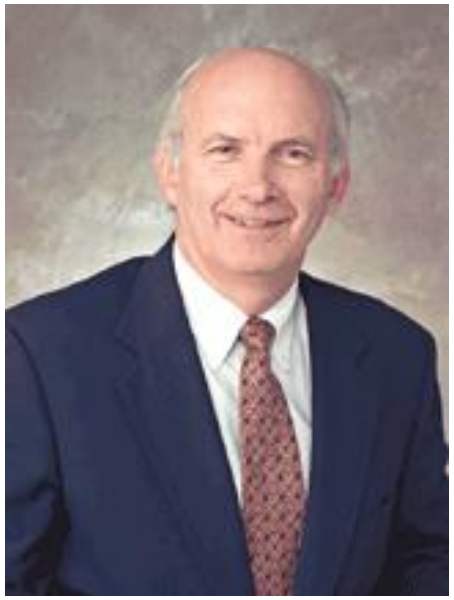
Dr. Takaji Wakita, National Institute of Infectious Diseases, Tokyo



Discoverer of the JFH-1 strain of HCV which grows in culture

HCV Affects Pathways Controlling Innate Immunity

Michael Gale Jr.
University Washington, Seattle



Stanley Lemon
UNC Chapel Hill

Adaptive Immunity and CTL Escape Mutations

Chris Walker, Columbus Children's Hospital, Ohio State University

Diagnosis of HCV infection: Antibody detection by ELISA

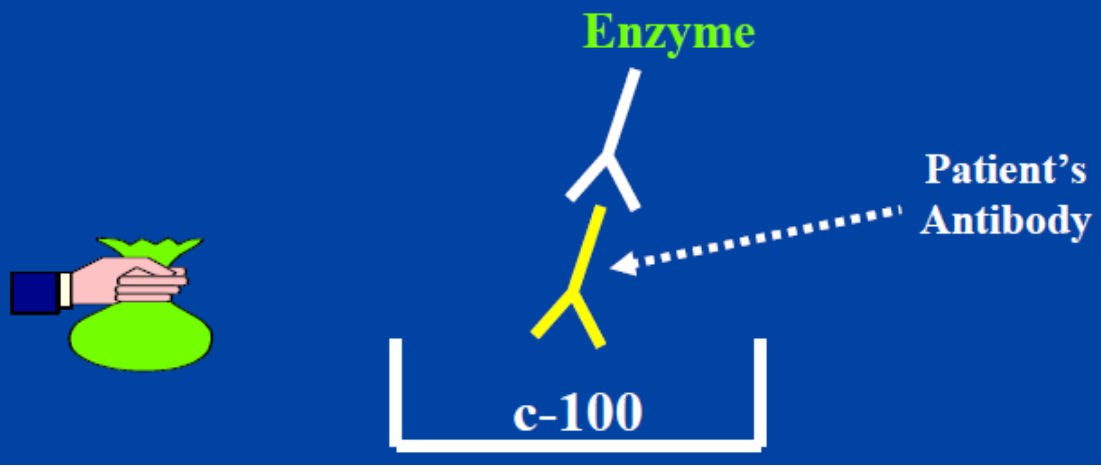
Identification, Cloning & Expression of Non-A, Non-B Virus Proteins - HCV

Wall Street Journal, May 11, 1988

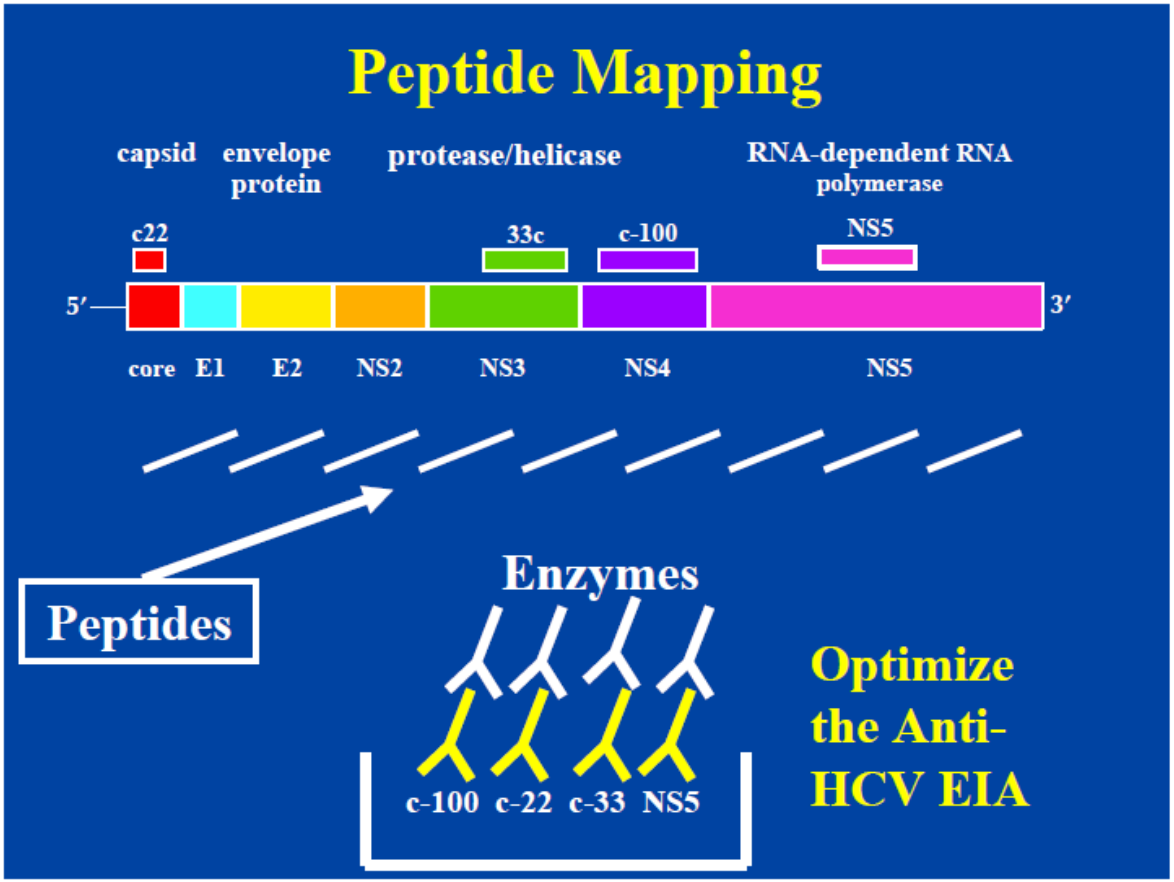
- **Identification & characterization without visualization**

  Choo et al. Science 1989;244:359-362; Kuo et al. Science 1989;244:362-364

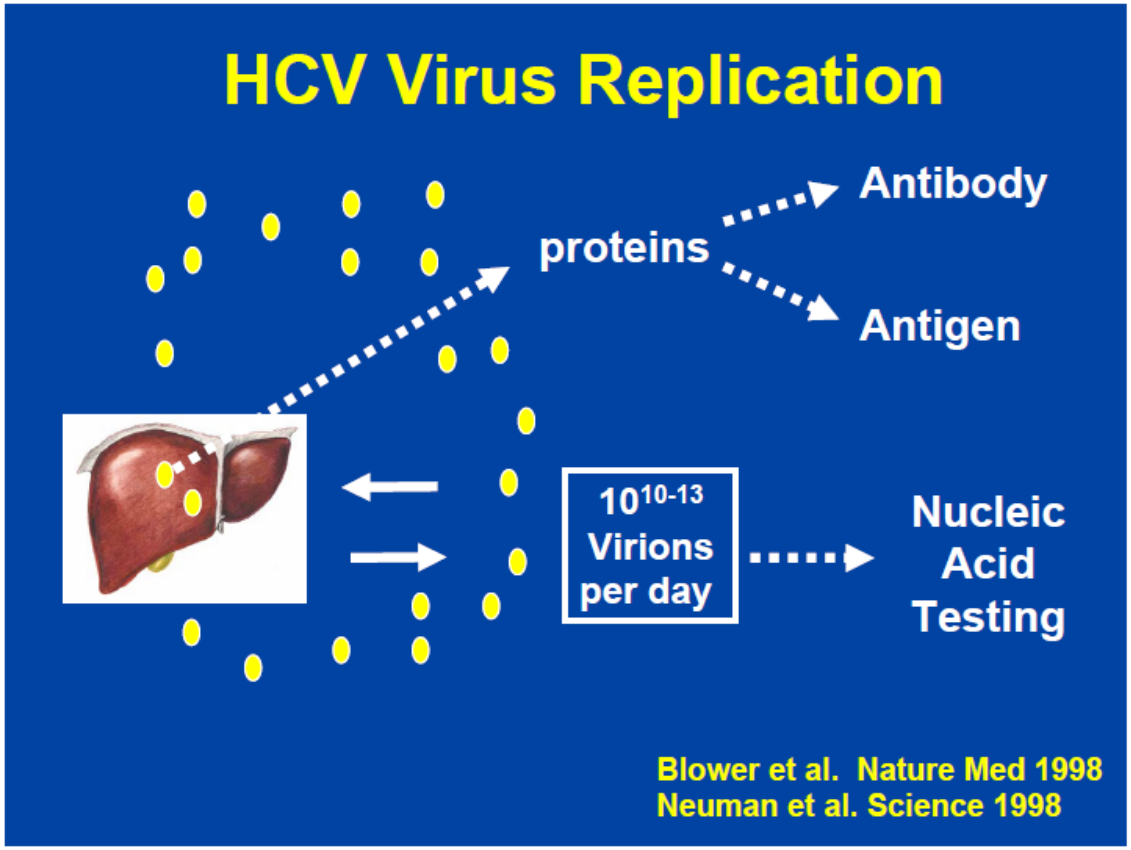
- **First generation anti-HCV enzyme immunoassay (EIA)**



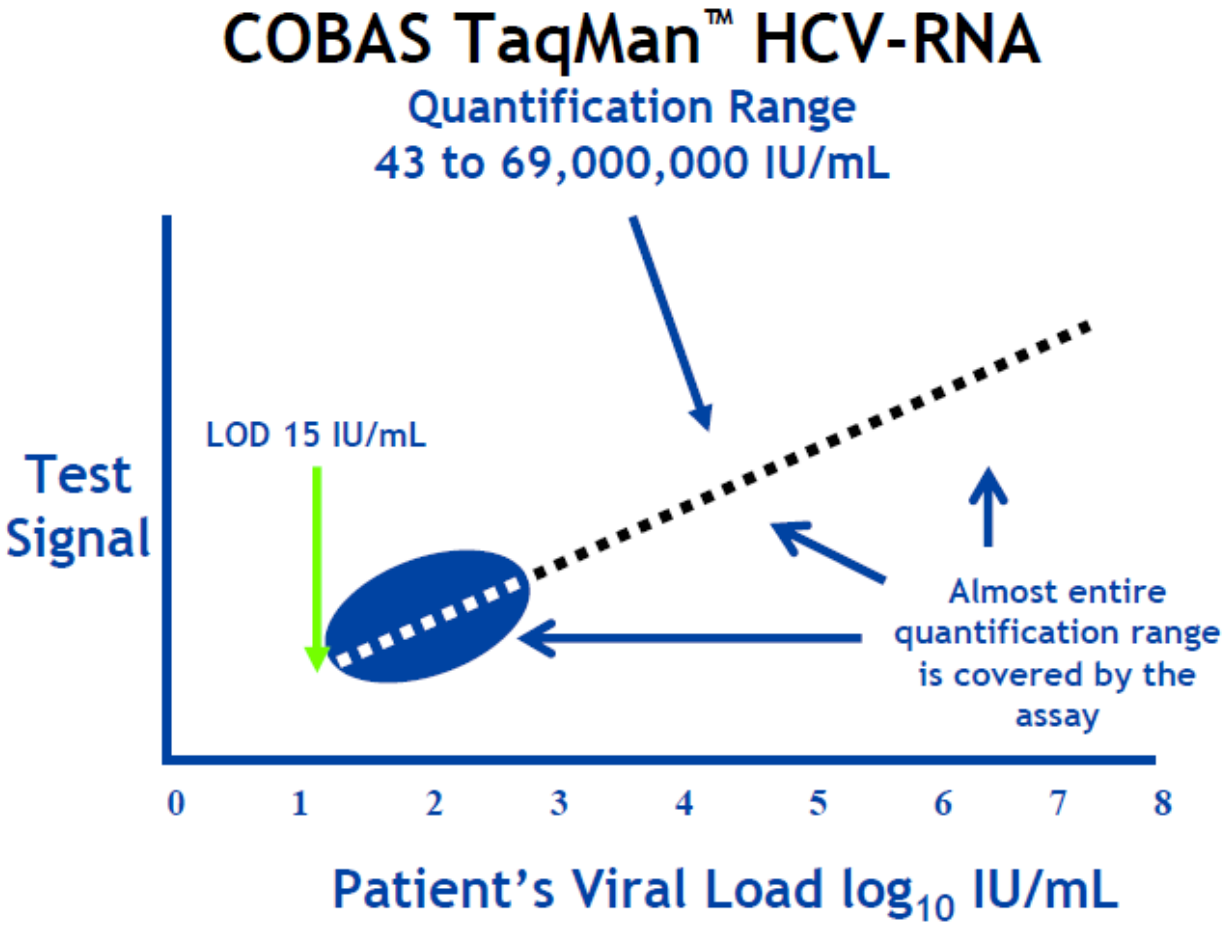
Increased sensitivity



HCV nucleic acid testing (NAT)



Most commonly used NAT for HCV



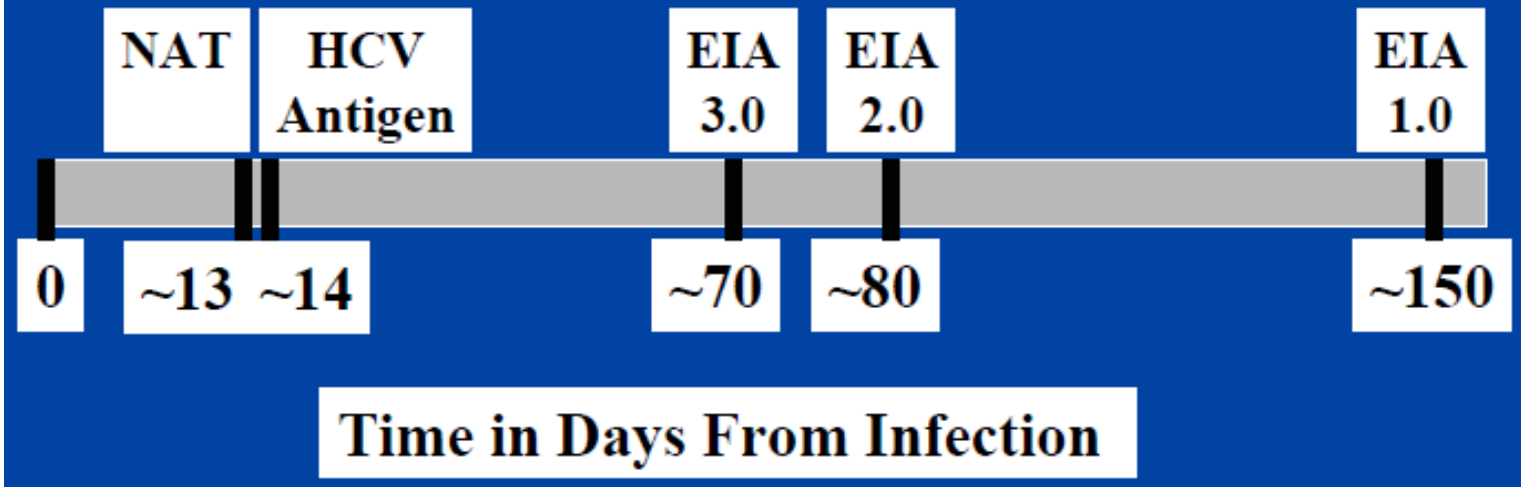
Early detection of HCV RNA by NAT

Improves EIA Sensitivity & Predictive Values

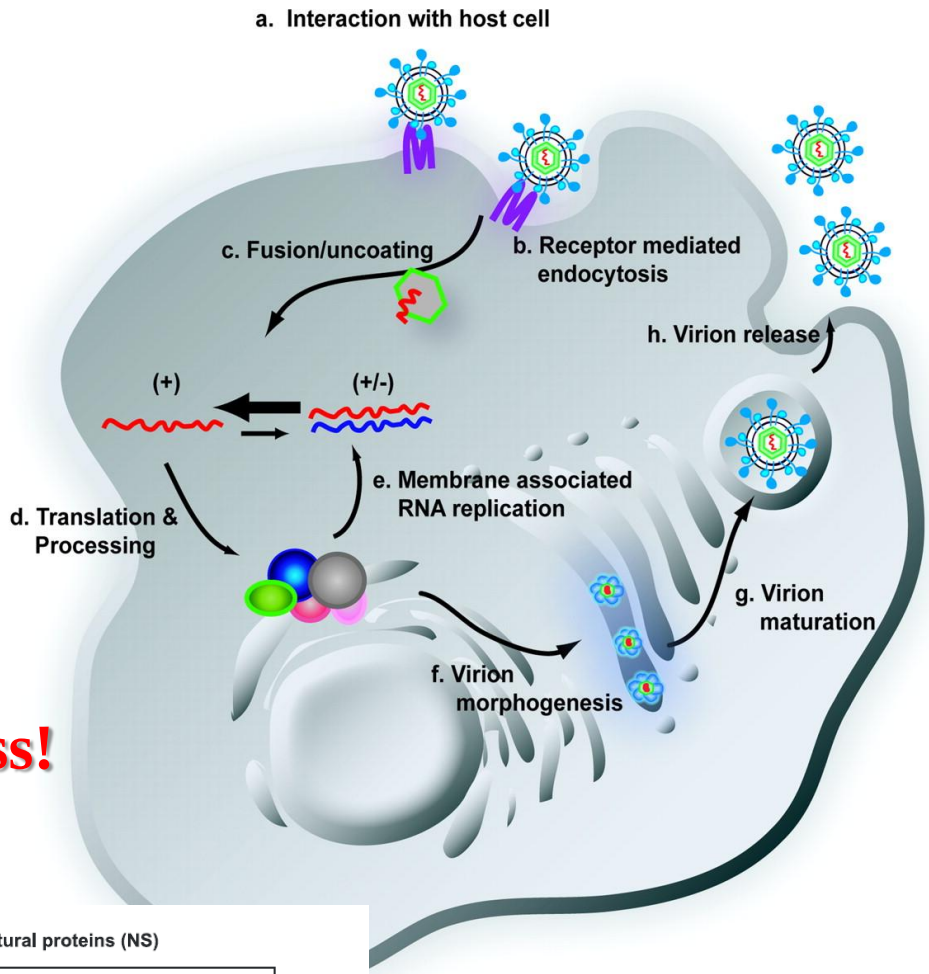
1st → 3rd generation anti-HCV EIA

- Sensitivity 70% → > 99%
- ↑ predictive value
- ↓ time between acute infection and detection

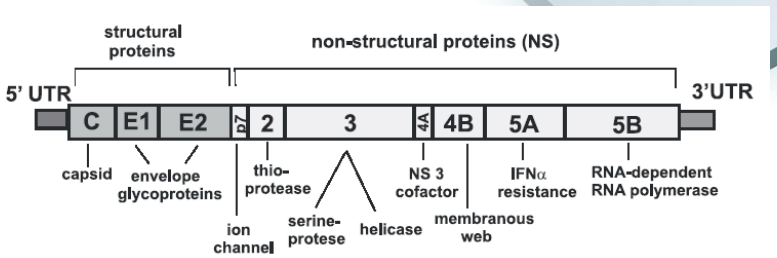
Gretch 97, Schiff 99, Pawlotsky 99, Krajden 2000



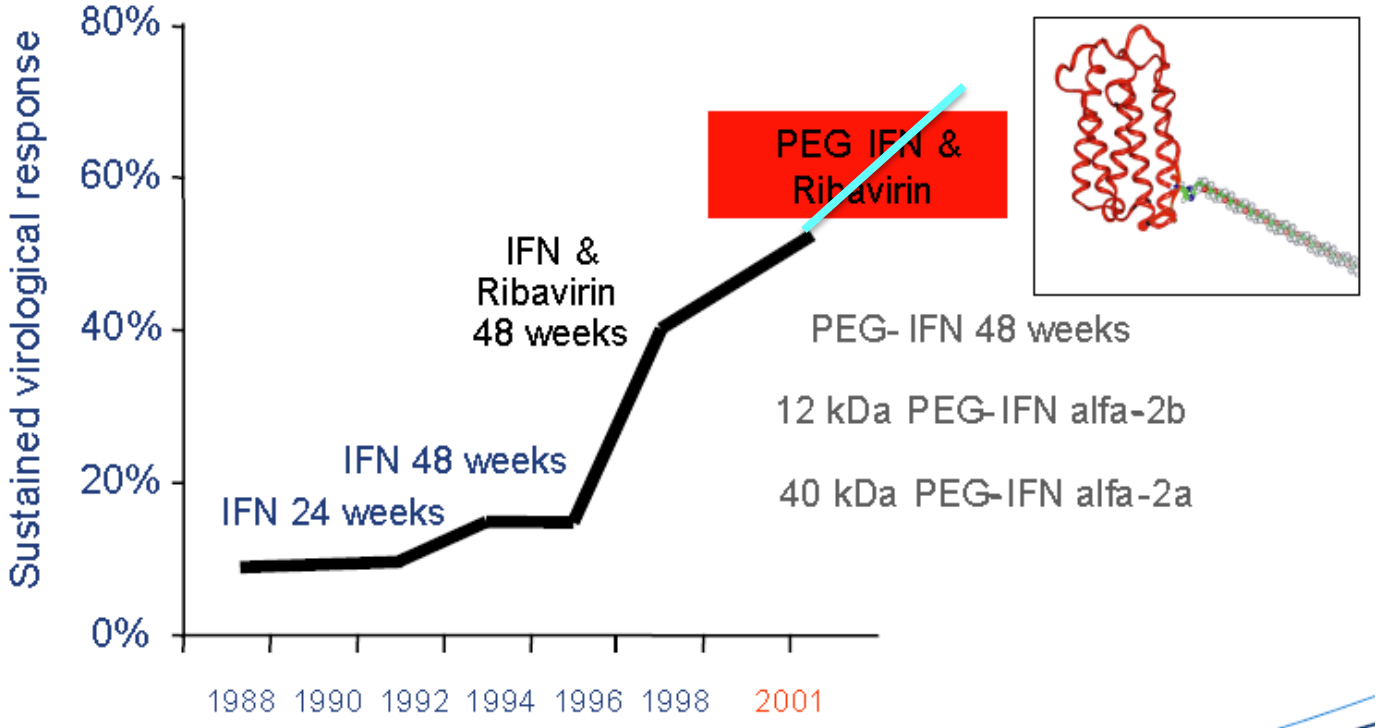
HCV life cycle



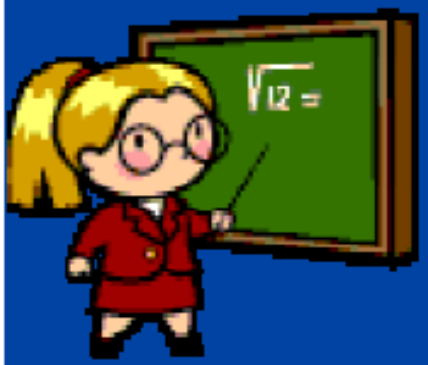
No RT process!



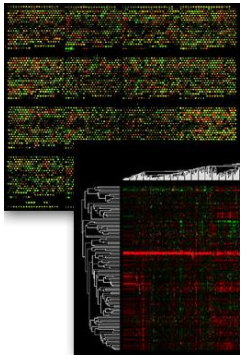
HCV treatment: IFN-based Standard of Care(SOC)



Pegylated Interferon/Ribavirin



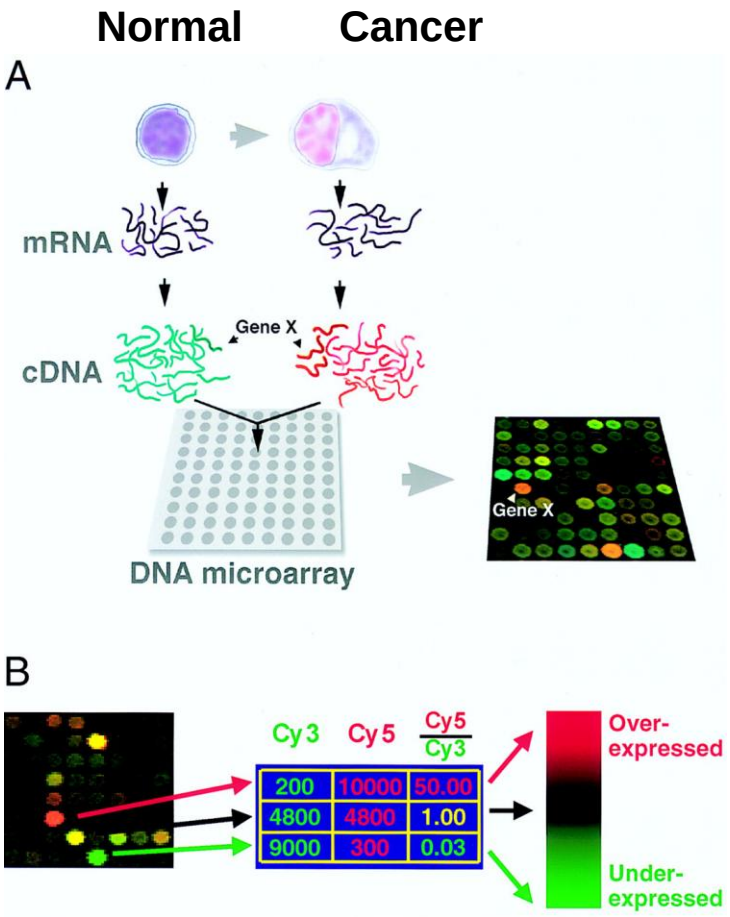
- Individualized therapy
  - viral/host factors
- Viral genotype → 6 major types
  - G1=61%; G2=14%; G3=23% & G 4, 5, 6 = 1%
    - Genotype
      - 1, 4, 5, 6 → cure rates of ~45% with 48 wks of Rx
      - 2 → cure rates of 80% to 90% with 24 wks of Rx
      - 3 → cure rates of ~75% with 24 wks of Rx



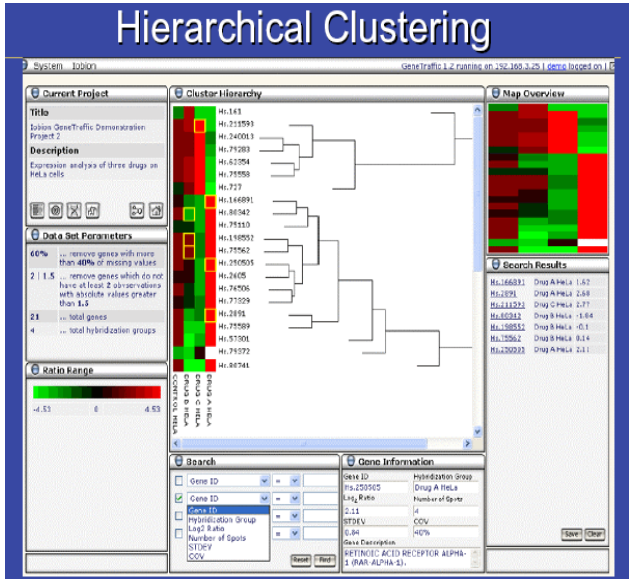
High through-put gene expression profiling

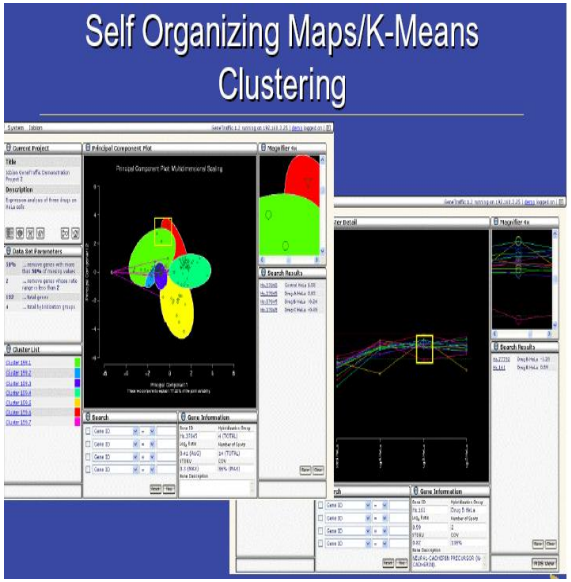
- Gene chip = Microarray
- Detect tens of thousands of mRNA at the same time
- Traditional/classical method: one or a few genes at a time
- Post-genomic HTP tools: study gene expression

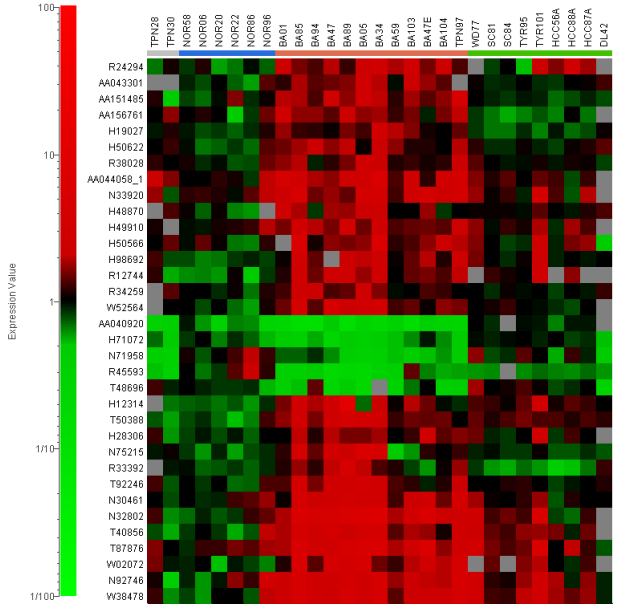
cDNA microarray

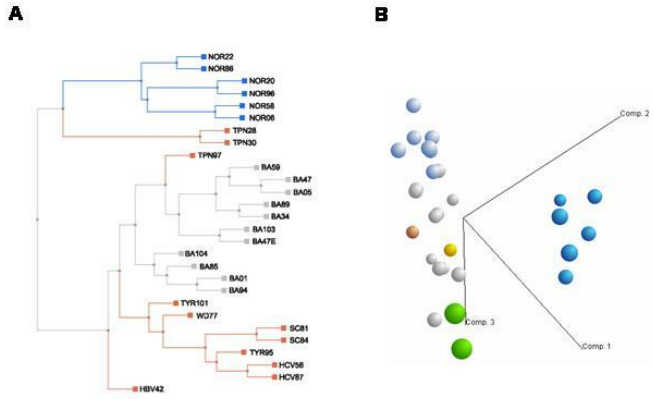


Data analysis is the key …









Part I: Introduction to HCV- summary

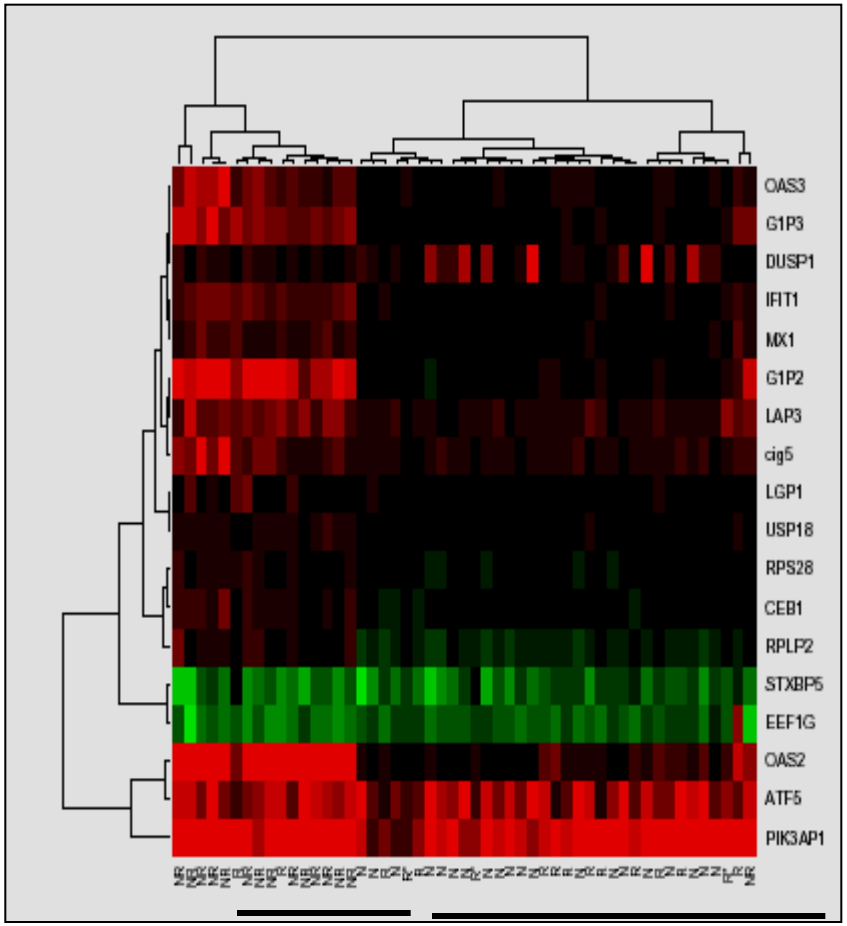
- HCV is a (+) strand RNA virus, hypervariable
- 170 million infected individuals (3%) worldwide
- No DNA phase, no genomic integration-curable disease
- 6 major genotypes: 1-6
- Diagnosis: ELISA for Antibody, NAT for RNA
- Treatment: IFN based+ DAA (from 2011)
- No vaccine- antibody not protective

Part II: Identification of HCV response signature by microarray gene expression profiling

Screen for gene signature for predicting treatment response in HepC

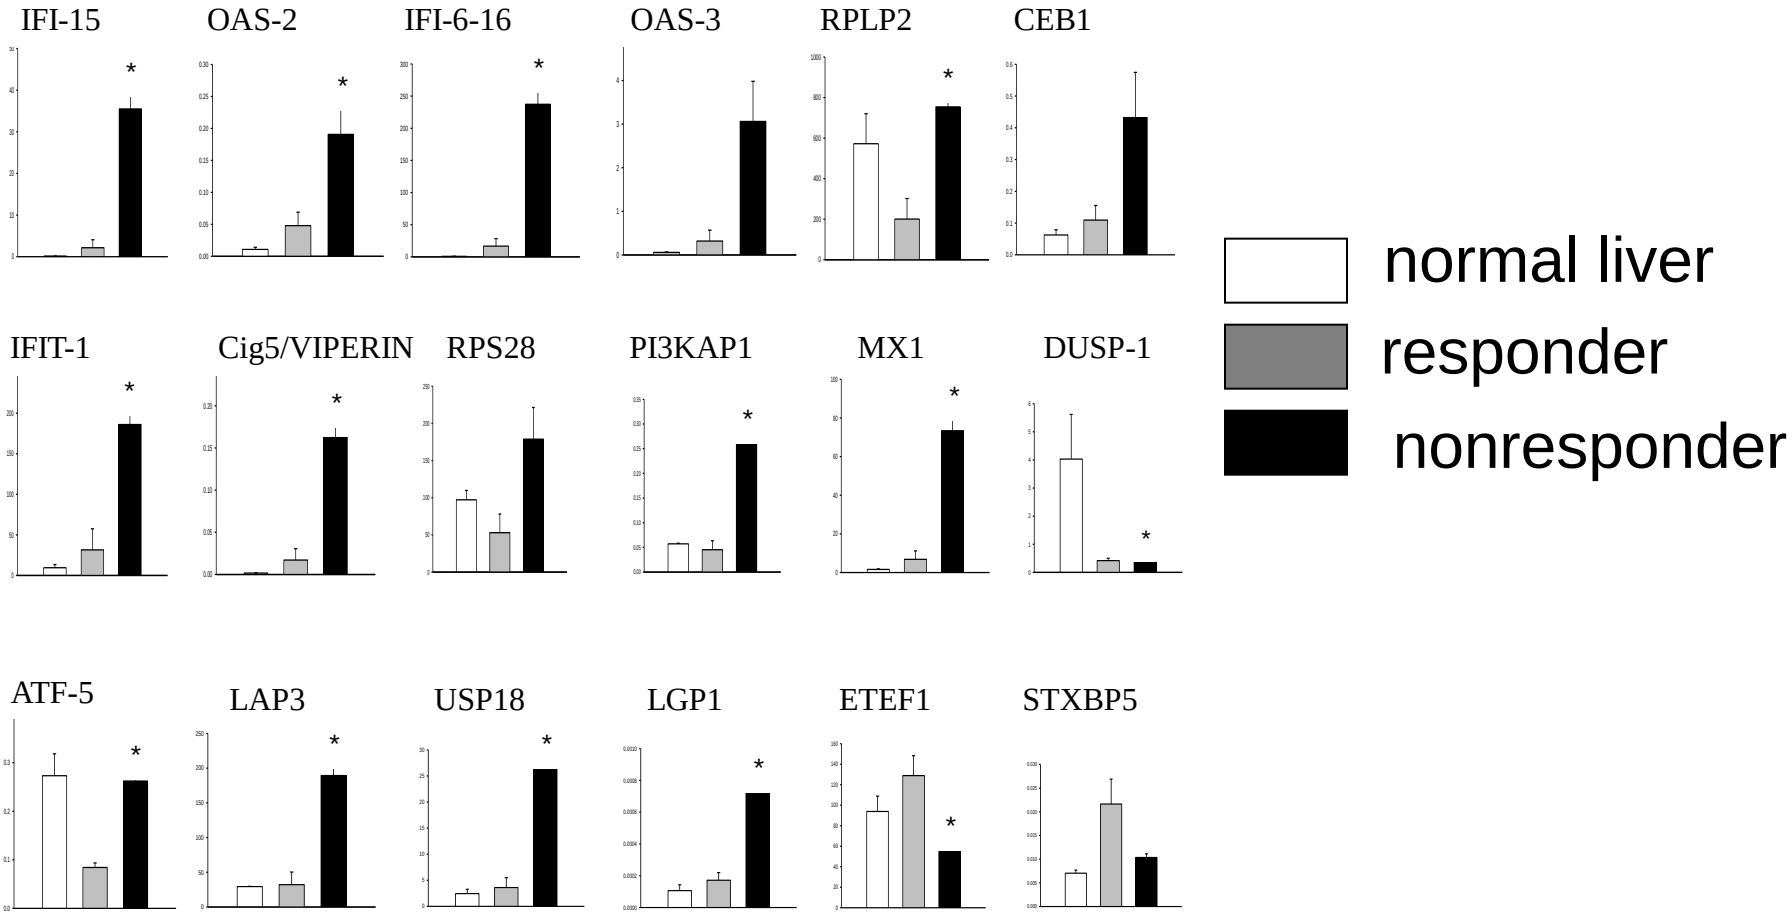
- 15 Non-responders and 16 Responders
- Biopsies prior to treatment
- Gene expression profiling done (19,000)
- Compare the difference between NR and SVR
- Generate gene signature

18 Genes Whose Expression Levels Are Statistically And consistently Different Between Responders (R) and Nonresponders (NR)



Chen, et al. *Gastroenterology* 2005

An 18-gene signature differentiates Responders and Non-responders



Chen, et al. *Gastroenterology* 2005

An 8-gene Subset Accurately Classifies 30 out of 31 patients

Genetic Markers Can Predict Response to Hep C Treatment

BY KATE JOHNSON
Elsevier Global Medical News

MONTREAL — A genetic signature involving 18 genes can reliably predict response to treatment with pegylated interferon α plus ribavirin in patients infected with hepatitis C, reported Dr. Limin Chen at Canadian Digestive Diseases Week.

This finding "could form the basis for a diagnostic tool to encourage treatment compliance," said Dr. Chen in an interview. The results also confirm the findings of in vitro studies by Dr. Chen's group, led by Dr. Ian McGilvray, Dr. Aled Edwards, and Dr. Jenny Heathcote from the University of Toronto.

His group previously identified gene expression differences in the pretreatment liver biopsies of hepatitis C virus (HCV) patients who subsequently responded, or failed to respond, to pegylated interferon α plus ribavirin, showing that these two groups "differ fundamentally in their innate [interferon] response to HCV infection" (Gastroenterology 2005;128:1437-44).

Upregulation of an 18-gene signature known as USP18 predicted lack of response to treatment, and another study by the same group demonstrated that silencing this particular gene signature in vitro could improve treatment response (Gastroenterology 2006;131:1584-91).

"We were able to show that if we silence this USP18 gene, the virus actually gets more sensitive to interferon. In other words, we can use much less interferon to kill the virus," Dr. Chen said.

The group's latest work validates the findings from a prospective cohort study of 78 HCV patients (mean age, 51 years): 23 nonresponders and 55 responders. Using pretreatment liver biopsies, "we confirmed that USP18 is more highly expressed in nonresponders," Dr. Chen explained.

The study determined that the genetic evaluation of pretreatment liver biopsies with regard to this gene signature can predict treatment response with a positive predictive value of 96%. However, the negative predictive value was only 50%, he said.

"In other words, [if you use] this gene signature, your prediction that someone would respond to treatment would be 96% accurate, but if you predicted nonresponse, you would have only a 50% chance of accuracy," he said. "Therefore, you cannot use it to exclude patients from treatment."

Dr. Robert S. Brown Jr. commented, "Better predictors of response are needed, but perhaps more importantly we need predictors of non-response. These data, if verified, could provide motivation to those patients who are predicted to have a high likelihood of success, but unfortunately will not spare patients who have a low likelihood of success from side effects." Dr. Brown is the Frank Cardile associate professor of medicine and surgery and chief of the division of abdominal organ transplantation at Columbia University College of Physicians and Surgeons, New York.

Current combination treatment with pegylated interferon α plus ribavirin has only a 50% success rate, and patient compliance with therapy is frequently jeopardized by the treatment's significant side effects and expense, according to Dr. Chen.

Genetic markers such as USP18 that predict good treatment response might help physicians encourage compliance in certain patients, he said at the meeting, which was sponsored by the Canadian Association of Gastroenterology. ■

Genomic Arrays Can Help Predict HCV Patients Who Will Likely Respond to PegIFNα Plus Ribavirin Therapy

PegIFNα plus ribavirin (PegIFN/rib) treatment is effective for treatment of chronic hepatitis C (HCV), but a significant number of patients do not respond to therapy for reasons that are unclear. Because of the substantial cost and side effects of this treatment, the ability to predict nonresponding (NR) or responding (R) patients would be clinically useful. The study by Chen et al attempts to develop a genomic analysis of liver biopsy samples to distinguish between the two groups. The investigators identified 18 genes whose expression differed significantly between all responders and all nonresponders, with $P < .005$. Several of these genes were interferon-responsive, reinforcing a paradigm relevant to treatment responses. On further analysis, an 8 gene subset was found that accurately predicted treatment response for most of the patients, applicable to genotype 1 patients, but not correlated with viral load, disease activity, or fibrosis (Figure 5). In conclusion, NR and R patients differ fundamentally in their innate interferon response to HCV infection. These differences likely reflect aspects of HCV pathogenesis and form the basis for a predictive subset of genes that can predict treatment responses prior to initiation of PegIFN/rib therapy.

Ubiquitin-Specific Protease 18 Expression Inhibits Interferon-Induced Hepatitis C Virus (HCV) Reduction in an In Vitro HCV Replication System

Interferon α (IFN), usually in combination with ribavirin, is a major component of the treatment regimen for controlling hepatitis C (HCV) viral infection in humans. Although some patients respond, more than half treated with IFN do not effectively clear the virus, which may be due to many factors including viral genotype and host response. Of factors identified that attenuate the host response to IFN for HCV infection is the up-regulated expression of ubiquitin-specific protease 18 (USP18), a protease that cleaves ubiquitin like (and IFN-induced) pro-

APASL : Presidential Award

22 April 2013

Limin Chen
Chinese Academy of Medical Sciences
Chengdu, China

Subject: **Presidential Awards**
APASL Liver Week 2013
6 – 10 June 2013, Singapore

Prof. Chen won the APASL presidential award

Dear Limin Chen ,

On behalf of the Local Organising Committee of the APASL Liver Week 2013, we are pleased to inform you that you have been selected as one of the recipients of the **APASL Liver Week Presidential Awards.**

Congratulations and we look forward to welcoming you to APASL Liver Week 2013 in Singapore!

Yours sincerely,

Seng Gee LIM
Congress Chairman
APASL Liver Week 2013, Singapore

Yock Young DAN
Chairman, Scientific Committee
APASL Liver Week 2013, Singapore

Have been invited to give talks…

- Internatioal conference on HCV(2005,Montreal, Canada; 2007, Glasgow, UK; 2009, Nice,France)
- International conference on interferon and cytokines (2006,Shanghai)
- AASLD(2006, Boston; 2008, San Francisco; 2009, Boston, 2010 Boston， 2011 SF)
- International conference on infectious diseases（ 2009,Beijing- sole Gold winner！）
- Invited to write reviews for J Hepatology,Int J Biochem & Mol Biol , Exp Rev Proteomics

Invited as key-note speakers & as session chairs

Invited as key-note speakers

Day 1: Wednesday, Nov 13, 2013

13:30-20:30 Ball Room

Hainan International Convention & Exhibition Center, Hainan, China

Podcast interview: www.gastro.org/gastropodcast. Also available on iTunes.

BACKGROUND & AIMS: Cell-type specific expression patterns of hepatic interferon-stimulated genes (ISGs) and single nucleotide polymorphisms (SNPs) near the *IL28B* gene are associated with response to interferon-based therapy in patients with chronic hepatitis C virus (HCV) infec-

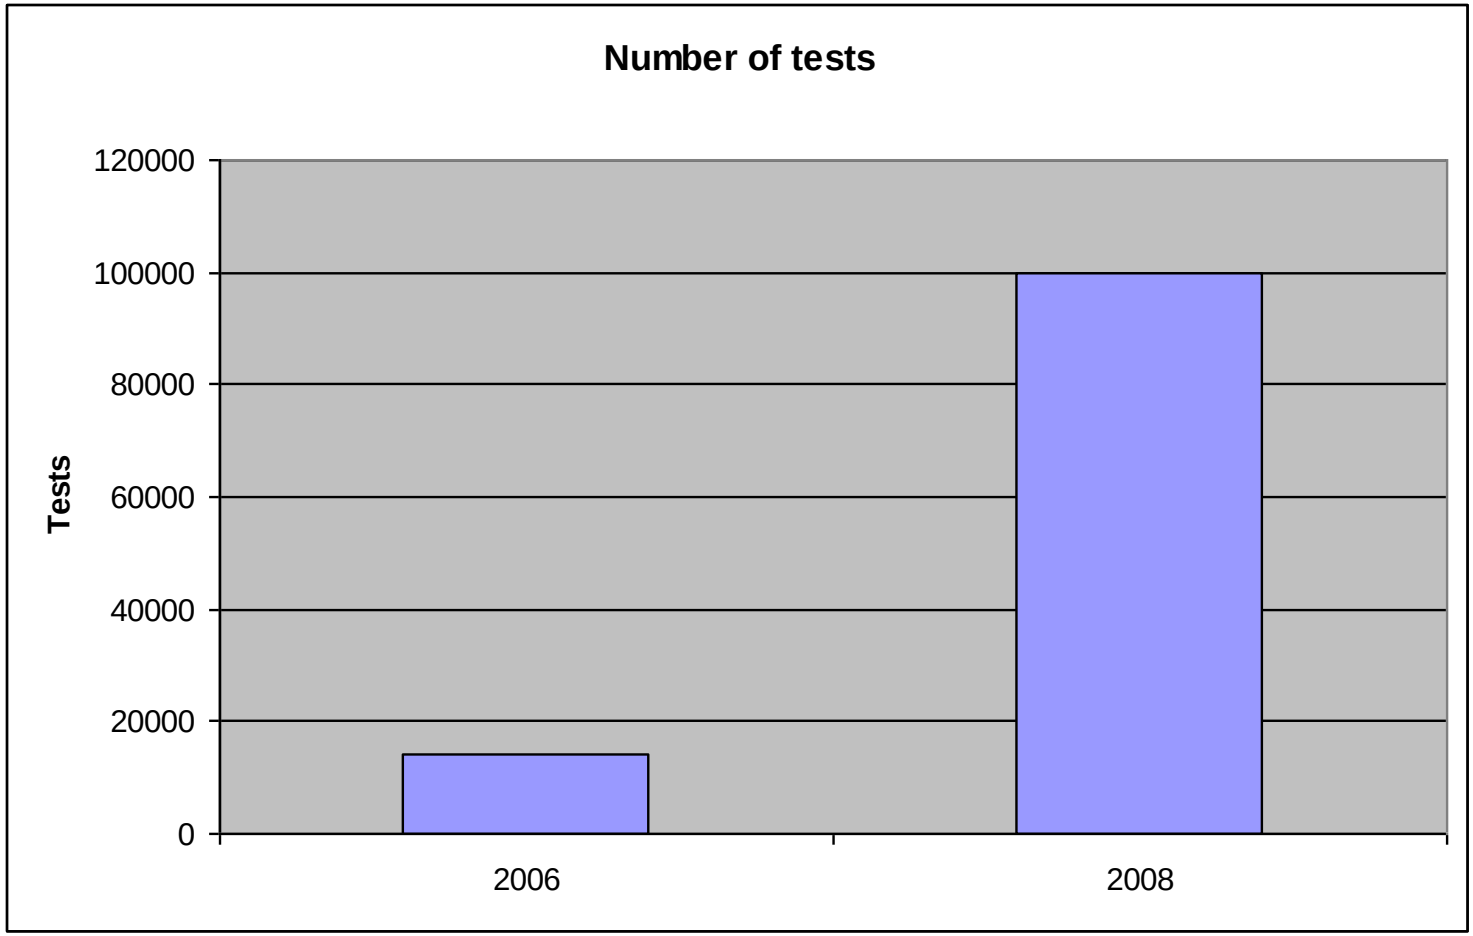
Keywords: Treatment Outcome; Prognostic Factor; Liver Disease; SVR.

The clearance of hepatitis C virus (HCV) requires a robust response to either endogenous or therapeutic interferon. HCV has evolved numerous strategies to circumvent interferon responses, leading to a high rate of chronicity after acute infection and sustained virologic response (SVR) rates of only 50% with peginterf
ribavirin.[1,2] Although direct acting antivirals (D

Potential market

- China: 40 million HCV, if 10% use this test, potential market valued **8 billion** Chinese Yuan. More infected patients due to no vaccine , bigger market up to **20-30 billions**.
- US：75,000-112,500 HCV genotype I infected（2015 increased by 5-fold）$**200 million /year ($ 1 billion/2015)**（$2000/test)（Oncotype Dx $3820/test)

Huge demand: Oncotype Dx predicts whether chemotherapy is necessary following breast cancer surgery: Increased by 7-fold in 2 years



2008 income: 100,000x $3,820/test = $382 million USD
