From sucking to swallowing deglutition by cortical or subcortical ways

Physiological swallowing and the abandonment of the suction are essential to build a beautiful occlusion. This acquisition occurs spontaneously for 60% of children at age 4 years; sample from which recruits children who will Never need orthodontic treatment. When the child require orthodontic treatment, acquiring a good swallowing will reduce the duration of treatment and ensure the stability of the results. This change in the swallowing program Can be done by cortical or subcortical ways.
