Case Report Open Access

Classical Wegener’s as Non Resolving Pneumonia

Department of Pulmonary Medicine, NRI General Hospital, Chinakakani, Guntur, Andhra Pradesh, India

Abstract

A 32 yr old female clinically and radiographically diagnosed as tuberculosis initially not responding to anti tuberculosis treatment was later on Diagnosed as classical Wegener’s granulomatosis basing on tissue biopsy, c-ANCA, along with other systemic manifestations posing a diagnostic challenge.

Keywords: Wegener’s granulomatosis (WG); Non resolving pneumonia; Renal biopsy; C-ANCA

Key Messages

High index of suspicion in non resolving pneumonia. Early diagnosis and prompt treatment of Wegener’s granulomatosis as disease progresses rapidly with renal involvement. Drugs used to treat WG are highly toxic, so definitive diagnosis is essential.

Introduction

Wegener’s Granulomatosis (WG) is an uncommon multisystemic disease of auto immune origin characterised by necrotising granulomatous vasculitis of small calibre vessels [1]. Clinical presentation is variable. Classical triad involving upper and lower respiratory tract and kidneys with other organs like ocular, cutaneous,rheumatological, neural, gastrointestinal and lower genitourinary systems.

Pulmonary and upper respiratory tract involvement occurs early. Involvement of lungs has been reported in up to 94% of patients [2]. It may present with isolated pulmonary symptoms [3] with chest radiographs showing nodular lesion of varying sizes, which may later cavitate (50%) consolidation of air space, ground glass opacification secondary to pulmonary hemorrhage, pleural effusion (10%), hilar and mediastinal lymph nodes (2-15%), airway narrowing leading to collapse.

We describe this case of WG as its was first thought to be tuberculosis and its diagnosis could not be made until other systemic manifestation and renal failure were present posing a diagnostic challenge.

Case History

A 32 yr old female presented with complaints of high grade fever, cough with scanty expectoration. She was on ATT since 5 months, had underwent cardiac surgery for large ASD 2 months back. On examination she had a temperature of 101 F, pulse rate of 120/min, BP: 120/80 mm Hg, RR: 22/min, SPO2 on Room air: 98%. On general examination pallor was present. Chest examination showed surgical scar over parasternal area with decreased air entry and occasional crepitations in right lower lobe area.

Initial investigations revealed

Chest Xray PA view (Figure 1)–consolidation patches in right mid and lower lung zones. HB-8.9 gms%; Total count-12,700 cells/mm³; DC-N83 L13 E01M03; ESR-130 mm/hr; Bleeding time-2'00"; Clotting time-4'00"; Peripheral blood smear- Hypochromic microcytic and predominantly normocytic anemia, neutrophilic leucocytosis. Widal test-negative; Complete urine analysis-normal; Blood for culture sensitivity-negative; Viral markers-negative; Sputum for AFB-negative; Sputum for grans stain–plenty of pus cells and budding yeast cells with pseudo hyphae seen. Sputum for c/s-candida species isolated; Blood grouping and typing-B+ve. She was started on IV antibiotics cefoperazone+sulbactum, tab fluconazole 150 mg od. Her ATT was continued. Anaemia was corrected with oral iron. There was no clinical response and her antibiotic regimen was changed to clarithromycin oral; IV amikacin and was discharged on request.

On revisit after 10 days, fever persisted with chest X-ray revealing no change in the opacities. She was advised HRCT which suggested (Figure 2): Thick walled irregular cavitary lesion seen at right mid zone with an adjacent pneumonic patch, Right loculated pleural effusion.

She developed conjunctivitis, arthralgia, and rash over nose and nasal septum, glossitis, which she declared as recurrence. As the pneumonia was not resolving she was further evaluated (Table 1).

In view of deranged renal function, renal biopsy was done and C-ANCA levels were sent, suspecting pulmonary renal syndrome. Renal biopsy revealed crescentic glomerulo nephritis (9/13) with significant immune deposits on IF studies consistent with pauci immune glomerulo nephritis. C-ANCA (pr3)-136.64 µ/ml (6 times normal).

A diagnosis of Wegener’s was made. She was started on IV methyl prednisolone and cyclophosphamide. Dramatic response was seen. Her urea creatinine levels reached normal levels with resolution of pulmonary infiltrates.

**Discussion**

The diagnosis of WG in this patient was challenging due to its atypical Presentation as non resolving pneumonia [4]. India is an endemic country for tuberculosis, first diagnosis to be considered is pulmonary tuberculosis.

A non resolving pneumonia with systemic manifestations, pulmonary renal syndrome [5] and renal biopsy along with c-ANCA [6], is a clue to final diagnosis as WG.

Diagnosis of WG is based on typical clinical and imaging features associated with pr 3-anca. A set of four clinical criteria including an abnormal urine sediment, abnormal chest X-ray, Oral ulcers and nasal discharge, granulomatous inflammation on biopsy were used in current clinical practice for diagnosis of WG. These criteria are 88% sensitive and 92% specific.

WG is a systemic small vessel vasculitis first described by winger in 1933, followed by Wegener in 1936, and Ringerts in 1947. It is a relatively uncommon disease with mean age of presentation 50yrs with equal male to female ratio. Onset is acute or sub acute but may be indolent. At presentation upper airway involvement is most common and manifest as sinusitis and nasal ulceration, otitis pain and hearing loss. Larynx and sub glotticregion is involved causing hoarseness and dyspnoea. Pulmonary involvement typically involves all the three components of lung parenchyma, air ways, and pleura. Radiographic changes occur in lungs in 50-75% at presentation.

Functional renal impairment is unusual at presentation being seen only in only 10% with Glomerulonephritis associated hematuria and proteinuria and can lead to renal failure if not treated aggressively. About 85% with multi organ involvement have pr3-anca positivity with sensitivity of 91% and specificity of 99% for active disease. The interesting point to be noted is individual pulmonary opacities with or without cavitation decrease in size or even disappear before therapy [7] which was apparent in this case on following serial X-rays (Figures 3 and 4).

Other systems like musculoskeletal system may involve at onset in 30% cases with arthralgias, arthritis, myalgias acute myositis and jaw claudication. Central nervous system is involved in 20% cases may manifest as Peripheral neuropathy, Central neuropathy, External opthalmoplegia, CVA, Seizures, Cerebritis. Peripheral nervous system involvement typically occurs as mononeuritis multiplex or polyneuritis. Eye manifestations occur in 10-15% as Conjunctivitis, Dacrocystitis, Scleritis, Proptosis, Visual loss, Diplopia.

**Table 1: Investigations & Results on further evaluation after readmission.**
involvement is uncommon and may cause congestive heart failure, cardiomyopathy and pericarditis, which is a result of vascular occlusion. Skin lesions like palpable purpura, pyoderma like ulcers, papules, petechiae, nodules, bullae and gangrene are seen at the onset in 10-15% cases.

A limited form of disease has also been described affecting lungs with or without upper respiratory disease but without renal and other systemic involvement' early diagnosis and prompt treatment is crucial, which is often delayed. Disease progresses rapidly without treatment. Untreated WG carries a poor prognosis with death occurring in about 5 months from renal failure. The drugs used to treat WG are highly toxic, a definitive diagnosis is therefore very essential. Once renal involvement is noticed the treatment should be very aggressive.

Treatment of WG is Prednisone initiated at 1 mg/kg daily for 1 to 2 months then tapered. Cyclophosphamide 2 mg/kg daily for at least 12 months, >90% improve and 75% remit. For the maintenance of remission switch over to azathioprine 2 mg/kg/day and to reduce toxicity of Cyclophosphamide there is some evidence that long term cotrimoxazole which reduces relapse rate.
