Pinnacle Health, USA

Chilaiditi syndrome is a rare syndrome which occurs in 0.025% to 0.28% of the population. In this condition, there is symptomatic disposition of the right colon between the liver and the right hemidiaphragm. The symptoms of the patients can range from acute bowel obstruction to being asymptomatic. Diagnosis of Chilaiditi syndrome is very important as it can lead to life-threatening complications like perforation, volvulus and bowel obstruction and is best achieved by doing CT-scan. We describe a case of 59 year old man who presented with abdominal distention and pain in the abdomen. Chilaiditi syndrome was diagnosed via radiological methods and the patient was sent to the long term acute care facility as he refused to opt for surgery. Thus it shows that air under diaphragm is not always a surgical emergency and not recognizing the pathognomonic sign may lead to needless intervention. The clinical manifestations, diagnosis and management of this syndrome have been analyzed.

Biography
Hansini Laharwani was graduated from Government Medical College, Akola in 2015. She is currently doing Residency in United States. She has submitted 5 abstracts in international conferences and meetings.
