

3rd Annual Meeting on Infectious Diseases, Microbiology & Beneficial Microbes April 27-28, 2022 | Webinar

Volume: 10

Glutathione Pathway and GST Polymorphisms in the Immune Response to SARS-CoV-2: The Missing Piece of the COVID-19 Puzzle?

Bene Ekine-Afolabi

University of East London, United Kingdom

The pandemic of **COVID-19** disease, a respiratory condition caused by a novel coronavirus (SARS-CoV-2) in December 2019, has been evidently effectively controlled by vaccines. As of 31st May 2021, there are 170,189,835 confirmed cases in over 240 countries with over 3,538,196 deaths. It is characterized by a myriad of both respiratory and non-respiratory symptoms. Most individuals with the infection will have mild symptoms that are naturally resolved by an active immune system. However, a subset of people with a higher risk of infection are the elderly and those with comorbidities such as heart disease, diabetes, asthma, and cancer. The human immune response against viral infection is mainly dependent on active T cell function. **Glutathione** (GSH), a ubiquitous tripeptide antioxidant known for homeostasis regulation and important in oxidative stress response, is essential for T cell effector functions through its regulation of metabolic activity. Glutamyl cysteine ligase (GCL) catalyzes the rate-limiting step of glutathione synthesis. Polymorphisms in this enzyme impedes glutathione synthesis. **Glutathione S-transferases** (GSTs) catalyze the conjugation of glutathione to xenobiotics, reactive oxygen species (ROS), toxins, and other cellular by-products. Alterations in the structure, function, or level of expression of GST genes could alter the ability of the cell to inactivate toxins, thereby aggravating the progression of infection. GST polymorphisms have been clearly associated with such comorbidities including various cancers and respiratory diseases. It is well known that oxidative stress is a major factor in the pathogenesis of **viral respiratory infections**. Evidently, full dosed individual is still susceptible to infection and severe illness from the virus with possible hospitalization. Recovery from infection is associated with traumatic pain and fatigue, breathlessness, and negatively impacted morbidity. It is therefore possible that GST polymorphisms may impair immune response against the **coronavirus**. To the best of our knowledge, the potential implications of GCLC & GST gene polymorphisms on SARS-CoV-2 infection have not been elucidated.

Biography

Bene Ekine-Afolabi is a graduate of River State University of Science & Technology in Applied Biology (Medical Microbiology option); with an MRes degree at University of East London, United Kingdom. She had her PhD. study & worked at the Department of Natural Sciences, Middlesex University, UK. Trained in practical approach to toxicology in drug development (American College of Toxicology/British Toxicology Society). Bene does research in Microbiology, Molecular Biology and Cancer: Her current focus of research (which has yielded eight designed models), is on the Investigation of molecular mechanism of colorectal cancer and due to the current pandemic, has been involved in drug development for COVID-19. Bene had Harvard University part-sponsored training in therapeutic research in Cancer Biology & Therapeutic. Bene has been involved in three published peer reviewed article, two manuscript awaiting publication, among which one is on COVID-19 and was submitted to the Chief Medical Officer of United Kingdom to assist in response to the pandemic.
