Diabetic Neuropathy: Emerging Victory of Antioxidants

Ivan M Petyaev and Yuriy K Bashmakov*

Type 2 Diabetes Mellitus (T2DM) is a systemic metabolic disorder associated with serious and often life-threatening complications. Diabetic neuropathy is a common complication affecting more than half of T2DM patients [1]. Neurological abnormalities affecting the distal lower extremities are known to appear in the early stages of T2DM and even in patients with pre-diabetes and abnormal glucose tolerance [2].

There is no widely accepted consensus on the treatment of neurological abnormalities in diabetics. No drugs have been specifically approved for patients with diabetic neuropathy. For decades pharmacological interventions aimed at the normalization of glucose turnover and hemoglobin A (1C) level have remained a mainstay of therapy for diabetic neuropathy patients [3]. Other pharmacological options include pain management (tricyclic antidepressants, serotonin-norepinephrine reuptake inhibitors, $\alpha 2\delta$ ligands, antiepileptics, opioids) and anti-inflammatory drugs [4]. Although innovative treatment approaches (gene therapy, stem cell therapy, use of neurotrophic and growth factors) are under development, their rapid introduction into routine clinical practice seems to be problematical [4,5]. Even though symptomatic treatment usually produces some temporary improvements in the health status of patients, the etiology- and mechanism-driven approach to the treatment of diabetic neuropathy is not available, remaining in its infancy due to lack of precise knowledge about the pathophysiological mechanisms underlying neurological defects in T2DM. It has been clearly shown for decades that diabetic neuropathy is a direct consequence of abnormal glucose turnover mirroring improvements and deteriorations in glucose homeostasis. Chronic hyperglycemia in T2DM leads to up to a four-fold increase in the neuronal glucose level which cannot be neutralized by anaerobic and glycolytic burst as happens in the muscle cells [6]. Glucose neurotoxicity develops due to the unique oxidative biochemistry of glucose leading to accumulation of free radicals in the neuronal tissue via non-enzymatic, enzymatic and mitochondrial mechanisms [7]. Hyperglycemia promotes the formation of $O_2^{\cdot -}$ superoxide through the polyol (sorbitol) pathway which is accompanied by non-enzymatic generation of Amadori products and the subsequent formation of advanced glycation end products [8]. Moreover, reactive oxygen species have been shown to be generated in the nitric oxide synthase, NAD(P)H oxidase and xanthine oxidase systems [9]. It is now believed that oxidative damage is a primary pathogenetic mechanism causing impaired axonal transport, structural breakdown of Schwann cells and subsequent abnormalities in the propagation of action potential [10].

Due to advances in the understanding of the mechanisms of oxidative stress it recently became feasible to target oxidative stress using in particular nutraceuticals with antioxidant properties. This may create an important novel strategy in the treatment of diabetic neuropathy. The latest developments in clinical and experimental diabetology fully support this assumption. The most exciting results come from the recently published multicenter randomized double-masked parallel Neurological Assessment of Thioctic Acid in Diabetic Neuropathy (NATHAN) 1 trial which involved 460 patients with mild to moderate distal symmetric diabetic polyneuropathy. It was well documented that four year treatment with α -lipoic acid led to clinically relevant improvement of neurological functions as evaluated by seven

nerve function tests in patients with diabetic polyneuropathy [11]. Although α -lipoic acid treatment did not affect the nerve conduction parameters in patients, the Neuropathy Impairment Score of the lower limbs (NIS-LL) was improved in the lipoic acid treatment group and worsened in the placebo [11]. Similar improvements in neurological functions were recently shown on a smaller scale in comparable clinical settings [12] and animal studies [13,14]. Therefore, despite of some limitations, the results of NATHAN-1 trial represent the first systematic and considerable piece of evidence revealing the therapeutic effect of an antioxidant in diabetic neuropathy confirmed by others. Such an outcome is particularly welcome due to multiple failures to show any clinically measurable effect of antioxidants in different clinical settings. α -lipoic acid, otherwise known as thioctic acid, is an orthomolecular nutrient with extremely potent free radical scavenging capabilities reported in different systems [15]. Besides reducing lipid peroxidation, α -lipoic acid has been shown to normalize microcirculation and insulin sensitivity, enhance endogenous superoxide dismutase, reduce ischemia-reperfusion syndrome and prevent apoptosis [16]. Generally, α -lipoic acid is well tolerated and has low toxicity. However, the results of the NATHAN 1 trial reveal a tendency towards a higher incidence of adverse effects in the treatment group as compared to the placebo. This issue could be addressed in the future by a lowering of the therapeutic dose or the use of other isoforms of the compound. The antioxidant properties of α -lipoic acid are mediated by balanced conversion of the compound to dihydrolipoic acid, a reduced metabolite [15]. It has been shown recently under in vitro conditions that dihydrolipoic acid has superior antioxidant potency when compared to α -lipoic acid [17]. Therefore assessment of in vitro and in vivo toxicity and the possible introduction of dihydrolipoic acid into therapeutic formulations may provide a reasonable solution for the reduction of adverse effects of lipoic acid.

On the other hand, the implications of the NATHAN 1 trial go far beyond the therapeutic use of α -lipoic acid in diabetes care. It has been shown recently that the effect of α -lipoic acid in diabetic neuropathy can be enhanced by other antioxidants, in particular superoxide dismutase [18]. Therefore it is plausible to assume that the effect of α -lipoic acid is unlikely to be attributable to its particular chemical nature but is rather related to the antioxidant properties of the compound. Indeed, many other nutrients (resveratrol, lycopene, soy isoflavones) with antioxidant properties have been shown in both *in vitro* and *in vivo* systems to have a significant positive impact on the complications of T2DM [19]. The success of the NATHAN 1 trial has opened the door for

new clinical trials which may unveil the possible benefits of antioxidant use in T2DM. However, there are multiple challenges to clinical use of nutrients with antioxidant properties. Unlike α -lipoic acid many of them are susceptible to auto-oxidation [20], have limited absorption [21] and/or can be rapidly metabolized by the gut microbiota [22]. Therefore stabilized formulations of antioxidants would be required for new clinical research projects.

Nevertheless, the success of the NATHAN 1 trial gives great inspiration to new attempts at micronutrient use in diabetes. It is important to realize that T2DM is a nutritional disorder arising entirely from excessive and/or unbalanced food intake. Therefore nutritional interventions as well as the selective use of different food ingredients seem to be a most appropriate and promising treatment option for T2DM. The idea of using food ingredients as medicinal agents originated in ancient times. In particular, Hippocrates' statement "Let food be your medicine and medicine is your food" provides a backbone for the current philosophy of T2DM management. The diverse and extremely powerful physiological effects of some food constituents, comparable to the effects of some pharmacological agents - has led to the introduction of the relatively new term 'nutraceuticals' whose potential therapeutic use in T2DM patients has yet to be further explored in well-designed clinical trials.
