**Abstract**

Totally 11 minerals were reported in the present study. There are about 7 (Sodium>Potassium>Magnesium>Calcium>Manganese>Iron>Zinc) minerals were reported in all sexes. Sodium was maximum and zinc was minimum in all sexes. Copper, mercury and cadmium were available in trace amount in all sexes. However, arsenic was in trace amount in berried females and totally absent in males and females. Among different sexes, berried females contain maximum amount of minerals (157.65 mg) followed by males (117.30 mg) and females (93.65 mg). From the study, berried females contains maximum amount of minerals than males and females. So it is recommended to consume berried females to get maximum minerals.

**Keywords:** Minerals; Copper; Mercury; Cadmium; Male; Female; Berried; *Charybdis natator*

**Introduction**

Nutrients play a vital role on physical growth and development, maintenance of normal body function, physical activity and health. Nutrition is a basic prerequisite to sustain life. Minerals constitute the micronutrients and are necessary for physiological and biochemical processes by which the human body acquires, assimilates and utilized food to maintain health and activity [1-3]. This not only promoting proper physical growth and development, but also in ensuring adequate immunocompetence and cognitive development. Low level of mineral causes some health problem [4-6]. Determination of mineral composition of crab is important for both checking raw material quality and labeling requirement in nutritional point of view. That kind of information gives the idea of choosing the best product for health. Studies on the mineral composition of crabs are very limited. That kind of information gives the idea of choosing the best product for health. So it is designed to determine the mineral composition of edible crab *C. natator*.

**Materials and Methods**

The male, female and berried females of *C. natator* were procured from Parangipettai (Lat. 11°21’ N; Long. 79°46’ E) landing centres. The carapace of the crabs was opened and the edible parts of muscle tissues were removed with sharp forceps. The removed muscle tissues were homogenized with pestle and mortar. The grounded muscles were then freeze dried and powdered and eventually stored in refrigerator for further analysis. To the 5 g of crab tissue samples, mixture of hydrochloric acid, nitric acid and perchloric acid at a ratio of 10:5:1 was added for digestion at 30°C. The digests were filtered suitably and hydrochloric acid, nitric acid and perchloric acid at a ratio of 10:5:1 for further analysis. To the 5 g of crab tissue samples, mixture of hydrochloric acid, nitric acid and perchloric acid at a ratio of 10:5:1 were homogenized with pestle and mortar. The grounded muscles were removed with sharp forceps. The removed muscle tissues were homogenized with pestle and mortar. The grounded muscles were then freeze dried and powdered and eventually stored in refrigerator for further analysis. To the 5 g of crab tissue samples, mixture of hydrochloric acid, nitric acid and perchloric acid at a ratio of 10:5:1 was added for digestion at 30°C. The digests were filtered suitably and aspirated in digital flame photometer (Modal No.CL 22D, Elico pvt, India), the values obtained were expressed in mg/100 g [7].

**Statistical Analysis**

The data were subjected to One-way analysis of variance (ANOVA) and the difference between means were determined by Duncan’s multiple range tests (P<0.05) using SPSS version 17.0.

**Results**

The mineral compositions of the *C. natator* muscle tissue are shown in Table 1 and Figure 1. Totally 11 minerals were reported in the present study. There are about 7 (Sodium>Potassium>Magnesium>Calcium>Manganese>Iron>Zinc) minerals were reported in all sexes. Sodium was maximum and zinc was minimum in all sexes. Comparatively berried females contain the maximum amount of minerals than males and females. Copper, mercury and cadmium were available in trace amounts in all sexes. However, arsenic was in trace amounts in berried females and totally absent in males and females. Among different sexes, berried females contain the maximum amount of minerals (157.65 mg) followed by males (117.30 mg) and females (93.65 mg).

**Table 1:** Mineral composition (mg/100 g) in the muscle of *C. natator* (Values are mean of three values ± SE).

Discussion

Marine foods are very rich sources of mineral components. The total content of minerals in the raw flesh of marine fish and invertebrates is in the range of 0.6-1.5% wet weight. Mineral components such as sodium, potassium, magnesium, calcium, iron, phosphorus and iodine are important for human nutrition [8]. Crustaceans are also good sources of various minerals and high quality protein. Crab meat is an excellent source of minerals, particularly calcium, iron, zinc, potassium and phosphorus [9-12]. Living organisms require trace amounts of some heavy metals including iron, cobalt, copper, manganese, molybdenum, strontium, vanadium and zinc. Excessive levels of these metals, however, can be detrimental to living organisms. Other heavy metals such as cadmium, lead and mercury have no known beneficial effect on organisms and their accumulation over time in the bodies of mammals can cause serious illness [13]. The fish and shellfish can absorb minerals directly from the aquatic environment through gills and body surfaces. Almost all the elements that occur in seawater are found to some extent in aquatic animals and these includes Na, K, Ca, P, Al, Ba, Cd, I, Cr, Pb, Li, Hg, Ag, St and Va. Eyo [14] reported that the mineral content of fish makes unavoidable in the diet, as it is a source of different minerals that contribute to good health.

The minerals are serving as components of bones, soft tissues (Sulfur amino acids, metalloproteins) co-factors and co-activators of various enzymes important in human nutrition. Calcium, phosphorus, magnesium and electrolytes (sodium and potassium) are considered to be as macro elements and iron, copper, zinc, iodine, chromium, cobalt, manganese, molybdenum, selenium are considered as trace elements that are required for normal functioning, for instance the more soluble minerals such as Ca, P, Na and Cl are involved in the maintenance of acid-base balance and membrane potential. The main functions of essential minerals include skeletal structure, maintenance of colloidal system and regulation of acid-base equilibrium. Minerals also constitute an important component of hormones, enzymes and enzyme activators [15].

Considering the elemental composition of common food items (dairy products, meat, fish, cereals and fruits), C. pagurus hepatopancreas is a good source of Ca, Fe, Cu, Zn and Se [16,17]. The more soluble minerals such as Ca, P, Na, K and Cl also have osmoregulatory function and the maintenance of acid-base balance and membrane potentials [18]. Some elements such as Mg, Al, Ca, Fe, Co, Cu and Zn are necessary for maintenance of optimum health thus are important from a nutrition point of view. Metals such as Pb, Cd, as and Hg are detrimental to optimum health and have toxilogical effect and the tissue samples are also used as the bio-indicator to assess bioavailability of contaminant concentrations in coastal water in environmental studies [19]. The aquatic environmental/ecosystem and their inhabitants are exposed and sensitive to the effects of environmental pollution from heavy metal contamination. Aquatic animals accumulate large quantities of these xenobiotics and the accumulation depends upon the intake and elimination from their body [20]. Among different aquatic organisms; oysters, crab and mussels, accumulate large quantities of heavy metals due to their habitat and feeding nature. Many metals (Co, Cu, Mn, Fe and Zn) are essential trace elements for aquatic organisms and are involved in biochemical processes such as enzyme activation.

Totally 11 minerals were reported in the present study. There are about 7 (Sodium>Potassium>Magnesium>Calcium>Manganese>Iron>Zinc) minerals are reported in all sexes. Sodium is maximum and zinc is minimum in all sexes. Comparatively berried female contains the maximum amount of minerals than males and females. These are very much comparable with the studies of Hagashi et al., Anon and Thirunavukkarasu [21-24]. Investigated the mineral contents of blue crab; C. sapidus and swim crab P. pelagius and suggested that Na, Ca, Zn, Cu values for blue crab and swim crab were not significantly different. Trace elements content in haemolymph of normal and red sternum mud crab were observed by Sancharoen et al. [25]. The mineral contents of green tiger shrimp and speckled shrimp were also found in both species showed seasonal differences (p<0.05), except the Ca content in green tiger shrimp. The average Ca contents of green tiger shrimp and speckled shrimp were 60.28 mg/10 g and 60.44 mg/10 g, respectively [26,27] reported the concentration of nine elements (Zn, Fe, K, Na, Mn, Cu, Mg, Ca, and P) in different tissues of crab meat and edible viscera of Chinese mitten crab, E. sinensis. Mohapatra et al. [19] studied the concentration of 10 elements (ppm) (K, Ca, Mn, Fe, Cu, Zn, Se, Br, Sr and Pb) in S. serata, S. tranquebarica, P. monodon, P. indicus and M. rosenbergi [24] assessed the minerals content of hard and soft shell crabs of P. sanguinolentus. In the present study calcium and magnesium alone contribute 50%. Sodium is maximum in berried females than males and females of C. natator. Similar results were reported in P. sanguinolentus [24], S. tranquebarica [23] and E. sinensis [27]. Ca also has an essential role in blood clotting, muscle contraction and nerve transmission. Calcium is nutritionally very important (up to 1.9% Ca is available in human body) and provides rigidity to the skeleton and plays a role in many metabolic processes [16]. It is also essential for hard tissue structure, blood clotting, muscle contraction, nerve transmission and osmoregulation and as a cofactor for enzymes procession [28]. The higher Ca content in male crabs are likely because this species has a sexual dimorphism, in which males have bigger claws and harder exoskeletons (composed of calcium phosphate). Particularly during the premoult period of C. pagurus, hepatopancreas accumulates Ca that is likely used in the exoskeleton calcification [29].

Magnesium is maximum in berried females than males and females. Magnesium was already reported in P. sanguinolentus [24], S. tranquebarica [23] and E. sinensis [27]. Magnesium is important for human nutrition and it is required for body’s enzyme system. In addition to maintain bone health, magnesium acts in all cells of the soft tissues, where it forms part of the protein-making machinery and necessary for energy metabolism. Mg is cofactor for enzyme systems [30].

Iron is maximum in berried females than males and females. Iron was already reported in E. sinensis [27]. Iron is one of the very important essential trace elements since it has several vital functions in the human system. It serves as a carrier of oxygen to the tissues from...
the lungs by red blood cell. Adequate Fe in the diet is very important for avoiding some major health problems [15]. Adequate iron in the diet is very important for decreasing the incidence of anemia, which is considered a major health problem, especially in young children. Iron deficiency occurs when the demand for iron is high, e.g., in growth, high menstrual loss, and pregnancy, and the intake is quantitatively inadequate or contains elements that render the iron unavailable for absorption [15]. Transition metal ions, particularly Cu and Fe, have been known as the major catalysts for oxidation [31]. Copper and iron are important minerals found in fish as respiratory pigment, while cobalt is present in vitamin B12.

Sodium contribution is maximum irrespective of the sex. In individual contribution sodium is the highest in berried females to get maximum minerals. So it is recommended to consume berried females of C. natator. Sodium was already reported in P. sanguinolentus [24], S. tranquebarica [23] and E. sinensis [27]. Sodium is the principal cation of the extra cellular fluid and regulator of its volume. Sodium also helps to maintain acid-base balance and is essential for nerve system. Potassium is maximum in berried females than males and females of C. natator. Potassium was already reported in P. sanguinolentus [24], S. tranquebarica [23] and E. sinensis [27]. Potassium is important to maintain the pH, storage and transfer of energy and nucleotide synthesis. Zinc is maximum in berried females than males and females of C. natator. Zinc was already reported in P. sanguinolentus [24], S. tranquebarica [23] and E. sinensis [27].

Zinc is an essential trace element for all living species, since it is an important component of several enzymes and plays an essential role in a number of biological processes involved in growth and development [16,32] reported higher Cu and Zn accumulation in females than males of semaphore crab. Manganese is maximum in berried females than males and females of C. natator. Manganese are important for the development of bones. It also acts as an activator of enzyme systems, but the connection with the deficiency symptoms in crustacean is not entirely clear. From the study berried females contains the maximum amount of minerals than males and females. So it is recommended to consume berried females to get maximum minerals.
