

Method proposed to prevent early (and maybe late) relapses in breast and other cancers

Michael Retsky

Department of Environmental Studies, Harvard TH Chan School of Public Health, USA

Abstract:

My colleagues and I have been studying a bimodal relapse pattern in breast cancer. This project started in 1993 when data from Italy and UK showed an unexpected bimodal relapse pattern in breast cancer. It seemed that 50 to 80% of all relapses in patients treated only with surgery occurred in an early wave of relapses in the first 3 years post-surgery. We have proposed a reasonable explanation over the years. It appears that the surgery to remove a primary tumor causes systemic inflammation for a week. During that time, dormant single malignant cells and avascular deposits escape from dormancy and appear as relapses within 3 years. The multi-national authors of these reports include medical oncologists, surgeons, anaesthesiologists, physicists and other scientists from several fields. A potential solution seems to exist based on our analysis, data, and retrospective studies. That therapy is the common inexpensive analgesic ketorolac administered as iv at the time of surgery and perhaps as oral drug for a few days after surgery. We edited a book in 2017 that was published by Springer-Nature (1) and a number of papers including one recently published (2). Other reports support this and suggest mechanisms (3-5).

Biography:

Michael Retsky received PhD in experimental physics from University of Chicago in 1974. He was working at Hewlett-Packard in Colorado Springs in 1982 when a friend started an informal cancer research project since

his wife was being treated for cancer. Over the next few years, Retsky became much more interested in cancer research than physics research. His first paper in oncology (Speer et al Cancer Research 1984) predicted that tumor growth included periods of dormancy. He eventually made a career change ending up on staff of Judah Folkman at Harvard
