Abstract

A new continuous numerical method based on the approximation of polynomials is here proposed for solving the equation arising from heat transfer along a thick steel slab and a hollow tube subject to initial and boundary conditions. The method results from discretization of the heat equation which leads to the production of a system of algebraic equations. By solving the system of algebraic equations we obtain the problem approximate solutions.

Keywords: Polynomials; Interpolation; Multistep collocation; Heat conduction

Introduction

The development of numerical techniques for solving heat conduction equation in science and engineering subject to initial and boundary conditions is a subject of considerable interest. In this paper, we develop a new continuous numerical method which is based on interpolation and collocation at some points along the coordinates (Odekunle, 2008). To do this we let \( U(x,t) \) represents the temperature at any point in the slab and the tube. Heat is flowing from one end to another under the influence of the temperature gradient \( \partial U/\partial x \). To make a balance of the rate of heat flow in and out of the media, we consider \( R \) for thermal conductivity of the steel, \( C \) the heat capacity which we assume constants, and \( p \) the density and \( D \) the thermal diffusivity of alcohol [1]. Heat flow in the slab is given by

\[
-R A \frac{\partial U}{\partial x} - R A \frac{\partial U}{\partial x} + \frac{\partial U}{\partial x} \frac{\partial U}{\partial x} = C \rho (Adx) \frac{\partial U}{\partial t} \tag{1.0}
\]

Heat flow through the tube is also given by

\[
-DB \frac{\partial U}{\partial x} - DB \frac{\partial U}{\partial x} + \frac{\partial U}{\partial x} \frac{\partial U}{\partial x} = C \rho (Adx) \frac{\partial U}{\partial t} \tag{1.1}
\]

Where \( A \) and \( B \) are the cross sections of the slab and the tube respectively.

The new method strives to provide solutions to the heat flow eqns. (1.0) and (1.1).

Solution Method

To set up the solution method we select an integer \( N \) such that \( N>0 \). We subdivide the interval \( 0 \leq x \leq x \) into \( N \) equal subintervals with mesh points along space axis given by \( x_i = ih, i = \frac{1}{h} N \), where \( N=1 \), similarly, we reverse the roles of \( x \) and \( t \) and we select another integer \( M \) such that \( M > 0 \). We also subdivide the interval \( 0 \leq t \leq T \) into \( M \) equal subintervals with mesh points along the time axis given by \( t_j = jk, j = \frac{1}{k} M \) where \( MK=T \) and \( h,k \) are the mesh sizes along space and time axes, respectively [2]. Here, we seek for the approximate solution \( \bar{U}(x,t) = \bar{U}_{ij} (x,t) \) of \( U(x,t) \) given by

\[
\bar{U}(x,t) = \bar{U}_{ij} (x,t) = \sum_{i=0}^{N-1} \sum_{j=0}^{M-1} a_i \bar{Q}(x,t) \text{, } x \in [x_i, x_{i+1}], \text{ } t \in [t_j, t_{j+1}] \tag{2.0}
\]

Over \( h > 0 \), \( k > 0 \) mesh sizes, such that

\[
0 = x_0 < ... < x_i < ... < x_N, 0 = t_0 < ... < t_j < ... < t_M, \rho \text{ is the sum of interpolation points along the space and time coordinates. That is, } \rho = g + b, \text{ where } g \text{ is the number of interpolation points along the space axis and } b \text{ the number of interpolation points along time coordinate. The basis function } \bar{Q}(x,t), r = 0,1,..., p - 1 \text{ is the Taylor's polynomials which is known, } a_i \text{ are the constants to be determined. There will be flexibility in the choice of the basis function as may be desired for specific application. For this work, we consider the Taylor's polynomials } \bar{Q}(x,t) = x^t \text{ [3-7].}
\]

The interpolation values \( \bar{C}_{j1},...\bar{C}_{j1+i} \) are assumed to have been determined from previous steps, while the method seeks to obtain \( \bar{U}_{i+j-k} \) (Odekunle, 2008). Applying the above interpolation conditions on eqn. (2.0) we obtain

\[
a_0 \bar{Q}(x_i, t_j) + a_1 \bar{Q}(x_i, t_{j+1}) + ... + a_p \bar{Q}(x_i, t_{j+p}) = \bar{C}(x_i, t_{j+p}) \tag{2.1}
\]

We let \( h = \frac{1}{\beta} \left( g \frac{2\beta - 1}{\beta} \right) \) arbitrarily and \( k = 0 \), then by Cramer’s rule, eqn. (2.1) becomes

\[
W = \left[ \begin{array}{c} \bar{Q}(x_i, t_j) \\ \bar{Q}(x_i, t_{j+1}) \\ \vdots \\ \bar{Q}(x_i, t_{j+p}) \end{array} \right], \text{ } a = \left[ \begin{array}{c} a_1 \\ a_2 \\ \vdots \\ a_p \end{array} \right]
\]

\[
W = \left[ \begin{array}{c} \bar{Q}(x_i, t_j) \\ \bar{Q}(x_i, t_{j+1}) \\ \vdots \\ \bar{Q}(x_i, t_{j+p}) \end{array} \right]
\]

\[
W = \left[ \begin{array}{c} \bar{Q}(x_i, t_j) \\ \bar{Q}(x_i, t_{j+1}) \\ \vdots \\ \bar{Q}(x_i, t_{j+p}) \end{array} \right]
\]

Where $z = i + g \left( \frac{2β - 1}{β} \right)$, $v = i - \frac{1}{β}$ and $W^{-1}$ exists (Odekunle, 2008). Hence, by equation (2.2) we obtain

$$a = \overline{a} \overline{E}, \quad \overline{a} = W^{-1}$$

(2.3)

The vector $a = (a_0, a_1, ..., a_p)$ is now determined in terms of known parameters in $\overline{a} \overline{E}$. If $\overline{a}_{i-1}$ is the $(i-1)^{th}$ row of $\overline{a}$ then

$$a_i = \overline{a}_{i-1} \overline{E}$$

(2.4)

Eqn. (2.4) determines the values [8-17]. Let us take first and second derivatives of eqn. (2.0) with respect to $x$

$$\overline{U}'(x,t) = \sum_{i=0}^p a_i \left[ Q'(x,t) \right]$$

(2.5)

$$\overline{U}''(x,t) = \sum_{i=0}^p a_i \left[ Q''(x,t) \right]$$

Substituting eqn. (2.4) into eqn. (2.5), we obtain

$$\overline{U}'(x,t) = \sum_{i=0}^p a_i \left[ Q'(x,t) \right]$$

Substituting eqn. (2.9) in eqn. (2.10) we have

$$\overline{U}'(x,t) = \sum_{i=0}^p a_i \left[ L_{i-1}E \left( Q' \left( x, t \right) \right) \right]$$

It is now determined in terms of known

If we obtain $\overline{a}_0 = \overline{a}_{i-1} \overline{E}$, then the calculated temperatures are

$$\overline{U}'(x,t) = \sum_{i=0}^p a_i \left[ Q'(x,t) \right]$$

(2.6)

We reverse the roles of $x$ and $t$ in eqn. (2.1) and we arbitrarily set $k = 0 \left[ \frac{1}{a} \right] \left[ b - \left( \frac{α-1}{a} \right) \right]$ and $h = 0$, by Cramer's rule eqn. (2.1) becomes

$$Ya = \overline{E}, \quad \overline{a} = \left( a_0, ..., a_p \right)$$

(2.7)

and [18-20]

$$\left[ Q_0 \left( x, t_0 \right), \quad Q_1 \left( x, t_0 \right), \quad ..., \quad Q_{p-1} \left( x, t_0 \right) \right]$$

$$Y = \left[ Q_0 \left( x, t_0 \right), \quad Q_1 \left( x, t_0 \right), \quad ..., \quad Q_{p-1} \left( x, t_0 \right) \right]$$

$$\overline{U}''(x,t) = \sum_{i=0}^p a_i \left[ \frac{Q''(x,t)}{\sqrt{q}} \right]$$

(2.8)

From eqn. (2.7) we obtain [4]

$$a = LE, \quad L = Y^{-1}$$

(2.9)

The vector $a = (a_0, ..., a_p)$ is now determined in terms of known parameters in $LE$. If $L_{i-1}$ is the $(i-1)^{th}$ row of $L$ then

$$a_i = L_{i-1}E$$

Also, eqn. (2.9) determines the values of $a_i$. Taking the first derivatives of eqn. (2.0) with respect to $t$, we obtain

$$\overline{U}'(x,t) = \sum_{i=0}^p a_i \left[ Q'(x,t) \right]$$

(2.10)

Substituting eqn. (2.9) in eqn. (2.10) we have

$$\overline{U}'(x,t) = \sum_{i=0}^p L_{i-1}E \left( Q'(x,t) \right)$$

(2.11)

But by eqn. (1.0) or (1.1) it is obvious that eqn. (2.11) is equal to eqn. (2.6), therefore,

$$\sum_{i=0}^p L_{i-1}E \left( Q'(x,t) \right) - \sum_{i=0}^p a_i \overline{E} \left( Q''(x,t) \right) = 0$$

(2.12)

Collocating eqn. (2.12) at $x=x_i$ and $t=t$, we obtain a new numerical scheme that solves eqns. (1.0) and (1.1) explicitly.

**Numerical Examples**

In this section we give some numerical examples to compute approximate solutions for equations (1.0) and (1.1) by the method discussed in this paper [5]. This is in order to test the numerical accuracy of the new method. To achieve this, we truncate the Taylor's polynomial after second degree and use it as the basis function in the computation. The resultant scheme is used to solve the following two problems.

**Example 1 (Eyaya, 2010)**

Given a 2 cm thick steel slab, solve for the temperatures as a function of $x$ and $t$ at $t=2.062$ seconds if the initial temperatures are given by the relation [24-26]. $U(0,t) = 100\sin \left( \frac{πx}{2} \right)$ where $k$ for steel is 0.13 cal/sec °cm, $c=0.11$ cal/g°C and $p=7.8$ g/cm³.

**Solution**

By simplification eqn. (1.0) becomes $\frac{∂^2 U}{∂x^2} = cp \frac{∂U}{∂t}$. To solve this equation we take $Δx = 0.25$ cm, then we find $Δt$ by the relation

$$\frac{kΔt}{Δx^2} = 2, \quad Δt = 0.825$$

We let $β=4, α=64$ arbitrarily which implies that $v = i - \frac{1}{4}, \quad z = i + \frac{1}{4}$ and $η = γ = i + \frac{1}{4}$. Taking two interpolation points along space coordinates and one along time implies that $g=2, b=1, p=3$ and for $i = \frac{1}{4}, \frac{3}{4}, ...$, and $j = \frac{1}{4}, \frac{3}{4}, ..., \frac{5}{4}, \frac{7}{4}, ...$, we obtain $h = \frac{1}{4}, 0, \frac{1}{4}$ and $k = \frac{1}{4}, \frac{1}{4}$, then the calculated temperatures are tabulated as shown in Table 1 [27].

**Example 2 (Eyaya, 2010)**

A hollow tube 25 cm long is initially filled with air containing 2% of ethyl alcohol vapors. At the bottom of the tube is a pool of alcohol from the surroundings to maintain a constant temperature of 30°C at which temperature the vapor pressure is 0.1 atm.). At the upper end of the tube, the alcohol vapors dissipate to the outside air, so the concentration is essentially zero. Considering only the effects of molecular diffusion, determine the concentration of alcohol as a function of time and distance measured from the top of the tube.

**Solution**

A hollow tube 25 cm long is initially filled with air containing 2% of ethyl alcohol vapors. At the bottom of the tube is a pool of alcohol from the surroundings to maintain a constant temperature of 30°C at which temperature the vapor pressure is 0.1 atm.). At the upper end of the tube, the alcohol vapors dissipate to the outside air, so the concentration is essentially zero. Considering only the effects of molecular diffusion, determine the concentration of alcohol as a function of time and distance measured from the top of the tube.

Molecular diffusion follows the law

\[ \frac{\partial c}{\partial t} = D \frac{\partial^2 c}{\partial x^2} \]

where \( D \) is the diffusion coefficient, with units in cm²/sec. For ethyl alcohol \( D=0.111 \) cm²/sec at \( 30^\circ C \), and the vapor pressure is such that 10 volume percent alcohol in air is present at the surface [7].

The initial condition is \( c(x,0)=3.0 \) and the boundary conditions are given by \( c(0,t)=0 \), \( c(25,t)=15 \). Since the length of the tube is 25 cm, we take \( \Delta x=5 \) cm using the maximum value permitted for \( \Delta t \) yields

\[ \Delta t = \frac{3}{32} \left( \frac{\Delta x^2}{D} \right) \cdot 0.111 \Delta t = 21.11 \text{ sec}. \]

If we take \( \beta=4 \), \( \alpha=3 \) arbitrarily then \( v = i - \frac{1}{4} \), \( z = i + \frac{1}{4} \) and \( \eta = \gamma = i + \frac{1}{3} \). Taking two interpolation points along space coordinates and one along time implies that \( g=2 \), \( b=1 \), implies that \( p=3 \) and for \( i = \frac{1}{3} \), \( j = \frac{2}{3} \), \( k = \frac{1}{3} \), \( \ldots \) we obtain \( h = -\frac{1}{4} \), \( 0 \), \( \frac{1}{4} \) and \( k = -\frac{1}{3} \), then the calculated concentrations of alcohol are tabulated as shown in Table 2.
