Abstract
Cabazitaxel is used to treat advanced prostate cancer. Cabazitaxel is a semi-synthetic derivative of the natural taxoid 10-deacetyl baccatin III with potential antineoplastic activity. Cabazitaxel is also known as XRP6258, a semi-synthetic taxane from a single diastereoisomer of 10-deacetyl baccatin III derived from the needles of various Taxus species. A stability-indicating high performance liquid chromatographic technique was developed for the determination of Cabazitaxel in bulk and pharmaceutical formulations. Chromatographic separation was performed on Shimadzu Model CBM-20A/20 Alite, using Zorbax SB-C18 column (150 mm×4.6 mm i.d., 3.5 µm particle size) with a mixture of 0.1% ortho phosphoric acid and methanol (20:80, v/v) as mobile phase with a flow rate of 1.0 ml/min. Cabazitaxel was subjected to stress conditions (acidic, alkaline, oxidation photolytic and thermal degradations and the method were validated as per ICH guidelines.

Keywords: Cabazitaxel; RP-HPLC; Stability-indicating; ICH

Introduction
Abazitaxel is used to treat advanced prostate cancer that is no longer responding to hormone therapy. It is also being studied for use against other kinds of cancer. It interferes with microtubules, which are part of the internal structure that cells need when they are dividing. This leads to cell death. Because cancer cells divide faster than normal cells, they are more likely than normal cells to be affected by this drug. Cabazitaxel is a semi-synthetic derivative of a natural taxoid used for the treatment of hormone-refractory prostate cancer [1]. Unlike other taxane compounds, this agent is a poor substrate for the membrane-associated, multidrug resistance (MDR), P-glycoprotein (P-gp) efflux pump and may be useful for treating multidrug-resistant tumors. Cabazitaxel binds to and stabilizes tubulin, resulting in the inhibition of microtubule depolymerization and cell division, cell cycle arrest in the G2/M phase, and the inhibition of tumor cell proliferation.

Cabazitaxel has been approved in the US by the Food and Drug Administration (FDA) [2] in June 2010 and in Europe by the European Medicines Agency (EMA) in January 2011 in combination with prednisone for the treatment of patients with castration resistant metastatic prostate cancer whose disease progresses after docetaxel treatment [3], based on the results of the TROPIC trial investigating Cabazitaxel plus prednisone versus mitoxantrone plus prednisone following docetaxel failure [4]. Cabazitaxel chemically known as (2aR,4S,4aS,6R,9S,11S,12S,12aR,12bS)-12b-acetoxy-9-(((2R, 3S)- 3-((tert-butoxycarbonyl) amino)-2-hydroxy-3-phenyl propanoyl) oxy)-11-hydroxy-4,6-dimethoxy 4a,8,13,13-tetramethyl-5-oxo-2a,3,4,4a,5,6,9,10,11,12,12a,12b-dodecahydro-1H-7,11-methanocyclodecabeno [1,2-b] oxet-12-yl benzoate is chemotherapy drug with molecular formula C45H57NO14 and molecular weight 835.93 g/mol (Figure 1) [5,6]. Cabazitaxel penetrates the blood-brain barrier. Cabazitaxel is currently being investigated in the setting of metastatic breast cancer progressing after taxane or anthracycline based chemotherapeutic regimens [7,8].

Very few analytical methods have been reported for the determination of Cabazitaxel such as spectroscopic techniques [9], HPLC [10,11], LC-MS/MS [12-14] in biological fluids. At present the authors have proposed a stability indicating RP-HPLC method for the determination of Cabazitaxel in presence of its degradation products.

Experimental

Chemicals and reagents
Cabazitaxel standard (purity 99%) was obtained from Dr. Reddy's Laboratories Ltd. (Visakhapatnam, India). Methanol (HPLC grade),
Polysorbate 80, Ethanol (HPLC grade), Sodium hydroxide (NaOH) and Hydrochloric acid (HCl), orthophosphoric acid and Hydrogen peroxide (H₂O₂) were purchased from Merck (India). All chemicals were of analytical grade and used as received.

Cabazitaxel is available as infusion with brand name Jevtana® (Sanofi-Aventis, Malaysia) with label claim of 60 mg of drug (60 mg cabazitaxel in 1.5 mL polysorbate 80 with diluent approximately 5.7 mL of 13% (w/w) ethanol in water for injection).

Instrumentation

Chromatographic separation was achieved by using Zorbax SB-C18 column (150 mm×4.6 mm i.d., 3.5 μm particle size) for HPLC system of Shimadzu Model CBM-20A/20 Allite, equipped with SPD M20A prominence photodiode array detector (maintained at 25 ºC) and LC Solutions 1.25 software.

Chromatographic conditions

Isocratic elution was performed using 0.1% orthophosphoric acid: methanol (20:80, v/v) as mobile phase. The overall run time was 10 min. with flow rate 1.0 ml/min with UV detection at 210 nm. 20 μL of sample was injected into the HPLC system.

Preparation of stock solution

Cabazitaxel stock solution (1000 μg/ml) was prepared by weighing accurately 25 mg of Cabazitaxel in a 25 ml volumetric flask with mobile phase. Working standard solutions were prepared on daily basis from the stock solution with mobile phase and filtered through 0.45 μm membrane filter prior to injection.

Method validation

The method was validated for system suitability, linearity, limit of quantitation (LOQ), limit of detection (LOD), precision, accuracy, selectivity and robustness [15].

Linearity test solutions for the assay method were prepared from a stock solution at different concentration levels (0.1–200 μg/ml) of the assay analyte concentration and 20 μL of each solution was injected into the HPLC system. The chromatogram of the blank as well as the drug solution was shown in Figure 3 respectively. The performance characteristics of the present chromatogram were recorded from which the percentage recovery was observed in the accuracy studies with % RSD 0.28-0.60 (2<.0%) (Table 3) indicating that the method is precise and accurate.

The limit of quantification and limit of detection were based on the standard deviation of the response and the slope of the constructed calibration curve (n=3), as described in ICH guidelines Q2 (R1) [15].

Precision was evaluated at three concentration levels (20, 50 and 100 μg/ml) against the qualified reference standard. The intra-day precision study was carried out by doing 3 independent assays for each concentration of Cabazitaxel and the mean as well as the % RSD were calculated for each concentration. The inter-day precision study was performed on three different days i.e. day 1, day 2 and day 3 at three different concentration levels (20, 50 and 100 μg/ml) and each value is the average of three determinations. The% RSD of three obtained assay values on three different days was calculated.

Standard addition and recovery experiments were conducted to determine the accuracy of the method. The study was carried out in triplicate at three different levels (80, 100 and 120%) and the percentage recovery was calculated. The accuracy study was performed by adding known amount of the standard (8, 10 and 12 μg/ml) to the samples which was prepared in our laboratory using the excipients. The study was carried out in triplicates and the percentage recoveries were calculated according to table 3.

The robustness of the assay method was established by introducing small changes in the HPLC conditions which included wavelength (208 and 212 nm), percentage of methanol in the mobile phase (78 and 82%) and flow rate (0.9 and 1.1 ml/min) and each value (Table 4) is the average of three determinations. Robustness of the method was studied for 100 μg/ml of Cabazitaxel.

As the marketed formulations were not available in India the drug was mixed with some of the common excipients used in the laboratory and extracted with the mobile phase. The percentage recovery was calculated from the calibration curve.

Forced degradation studies

Forced degradation studies were performed to evaluate the stability indicating properties and specificity of the method [16]. All solutions for stress studies were prepared at an initial concentration of 1 mg/ml of Cabazitaxel and refluxed for 30 min at 60°C and then diluted with mobile phase. 1.0 mg/ml Cabazitaxel solution was exposed to acidic degradation with 0.1 M HCl for 20 min at 60°C the stressed sample was cooled, neutralized and diluted with mobile phase. Similar stress studies were conducted in alkaline conditions with 0.01 M NaOH at 60°C for 20 min. and neutralized after cooling with proper dilution with mobile phase. Oxidative stress studies were performed using 30% H₂O₂ and thermal stress studies were conducted in thermostat at 60°C for 20 min. 20 μL solution of each of these solutions which were exposed to forced degradation studies were injected in to the HPLC system and the chromatograms were recorded from which the percentage recovery as well as the degradants were studied.

Results and Discussion

Method optimization

Initially the stressed samples were analyzed using a mixture of 0.1% ortho phosphoric acid: methanol (45:55, v/v) with a flow rate of 1.0 ml/min in which the peak shape was not symmetrical. Then the mobile phase composition was slightly modified with 0.1% ortho phosphoric acid: methanol (20:80, v/v) where a sharp peak was eluted at 4.24 ± 0.02 min without tailing (UV detection 210 nm) which was taken as the best chromatographic response for the entire study. The typical chromatogram of the blank as well as the drug solution was shown in Figure 3 respectively. The performance characteristics of the present stability indicating liquid chromatographic method was compared and discussed with the previously published methods in Table 1.

Method validation

Cabazitaxel has shown linearity 0.1-200 μg/ml (Table 2) (% RSD 0.11-0.54) with linear regression equation

\[
y = 21017x + 3853.9 \quad (r^2=0.9999)
\]

The LOQ was found to be 0.0967 μg/ml and the LOD was found to be 0.0319 μg/ml (Figure 2).

The % RSD range was obtained as 0.23-1.43 and 0.21-0.51 for intra- and inter-day precision studies respectively and 98.95-99.43% of recovery was observed in the accuracy studies with % RSD 0.28-0.60 (<2.0%) (Table 3) indicating that the method is precise and accurate.

The robustness of an analytical procedure refers to its ability to remain unaffected by small and deliberate variations in method parameters and provides an indication of its reliability for routine
analysis. The results obtained (Table 4) from assay of the test solutions were not affected by varying the conditions and were in accordance with the results for original conditions. The % RSD was less than 2.0% (0.19-1.66) indicating that the proposed method is robust.

As the marketed formulation was not available the drug was mixed with different excipients available in the laboratory and then extracted using the mobile phase. The proposed method was applied to the laboratory prepared formulation and the percentage recovery was calculated as 97.84.

**Forced degradation studies**

The stability indicating capability of the method was established from the separation of Cabazitaxel peak from the degraded samples. The typical chromatograms obtained from the forced degradation studies were shown in Figure 3. Cabazitaxel has shown 19.48% degradation with degradant at 1.736 min during acidic stress indicating that the drug is sensitive towards acidic environment. The amino group present in the drug structure may be highly responsible for this degradation. Cabazitaxel has undergone complete decomposition with degradants 1.667 min, 1.992 min and 2.571 min at during alkali stress indicating that the drug is very much sensitive towards alkaline condition. In other degradations the drug has undergone decomposition slightly (<15.0%). Decomposition was seen on exposure of Cabazitaxel solution to acidic (19.48%), alkaline (99.72%), oxidative (0.17%) thermal (1.03%) and photolytic (3.02%) conditions (Table 5). It is concluded that Cabazitaxel is very much sensitive towards alkaline conditions.

The present stability-indicating method for the determination of

Table 2: Linearity of Cabazitaxel.

![Figure 2: Calibration curve of Cabazitaxel.](chart)

![Table 2: Linearity of Cabazitaxel.](chart)
Cabazitaxel in pharmaceutical formulations is specific because the drug peak was well separated even in the presence of degradation products. The system suitability parameters for the Cabazitaxel peak shows that the theoretical plates were more than 2000 and the tailing factor was less than 2 (or <1.5-2.0) (Table 5).

**Conclusion**

The proposed stability-indicating liquid chromatographic method for the determination of cabazitaxel is economical as acetonitrile was replaced with methanol and the method can be applied for the assay of pharmaceutical dosage forms. Cabazitaxel is very much sensitive.
towards the alkaline conditions and it can be very easily undergoes decomposition.
