Abstract

The oil from *Moringa oleifera* seeds obtained from Afon in Asa Local Government Area of Kwara State, Nigeria, was extracted using n-hexane. The oil yield determined experimentally was 26.2%. The oil concentration was compared with those reported by [1,2]. Some physicochemical properties like the density, specific gravity, refractive index, pH, viscosity, acid value, peroxide value, saponification value, iodine value and FFA were determined. The results obtained were compared against previously reported data.

Keywords: *Moringa oleifera*; n-Hexane; Fatty acids; Physicochemical properties

Introduction

The Moringaceae is a single genus family of oil seed tree with 14 known species. *Moringa oleifera* is the most widely known and utilized. Moringa oil comes from the seeds of *Moringa oleifera* tree, a fast growing leafy tree species native to the Himalayas. *Moringa oleifera* contain between 33 and 41% w/w of vegetable oil.

The oil extracted from Moringa is known as Ben oil and reportedly contains 70% of oleic acid, an 18-carbon long monounsaturated fatty acid. Because the oleic acid has good oxidative stability when compared with polyunsaturated fatty acids, it has found use in the food industry, as it allows for longer storage and high-temperature frying processing. Another potential use of Moringa oil is as biodiesel feedstock. It also has uses in medicine and water treatment [3].

In this study, experimental results of solvent soxhlet extraction using n-hexane are reported. Solvent extraction has been reported by both Tsaknis et al. [1,2] and Palafox et al. [3]. Experimental results obtained from this research work will be compared with those obtained by the two scientists mentioned above.

Materials and Methods

Material and Sample Preparation

The *Moringa oleifera* seeds used were obtained from Afon in Asa Local Government Area of Kwara State, Nigeria. The pods were removed from the seeds to get the nuts inside. The nuts were then sundried in the open floor for a certain period of time to reduce the moisture content of the seeds and also for easy detachment of the seeds from the nuts.

After the seed has been separated from the nuts, they were dried in an oven at 105°C for 8 hours until a constant weight was obtained. The dried seeds were later ground into powder (approximately 2 mm particle size) using a hand-operated mortar.

Soxhlet extraction method

The Franz Von soxhlet extractor described by the AOAC (Association of Official Analytical Chemists) method was used for the extraction. The solvent used for the extraction was n-hexane.

About 100 g of the ground *Moringa oleifera* seeds were loaded into the soxhlet apparatus set. The extraction was carried out at 68°C (boiling temperature of n-hexane) for 10 hours.

Supernatant solution was collected which was the mixture of the extracted oil and the n-hexane. The suspension present in the solution was removed by filtration. After filtration, the solvent was eliminated in a rotavapor and the yield was calculated as grams of oil extract divided by grams of total seeds used.

Physicochemical analysis

Chemical analysis: The chemical properties such as iodine value (IV), saponification value (SV), acid value (AV), and peroxide value (PV) were determined by the method described by AOAC method (Association of Official Analytical Chemists).

Physical analysis: The physical properties such as density (ρ), refractive index, and viscosity (γ) of the oil extracted were also determined.

Results and Discussion

Experimental data

Yield was defined as grams of extracted oil divided by grams of total seeds used. The results obtained for the solvent extraction of Moringa oil including the physicochemical properties is presented in the table below. The oil content of *Moringa oleifera* (Nigeria), its physical and chemical properties are shown in Table 1. The oil content and the physicochemical properties were compared with the results obtained by Tsaknis et al. [1,2] in Table 2.

The oil content of the *Moringa oleifera* (Nigeria) was found to be relatively low compared with Tsaknis et al. [1,2], this may be due to difference in locations and moringa oil genotypes. The seed oil content depends on the genotype but it is also affected by the environmental conditions, cultural practices and time of harvesting [4].

The results of some of the physicochemical properties like the density, refractive index, viscosity and saponification value obtained

Table 2: Characteristics of the *Moringa oleifera* seed oil compared with Tsaknis et al. [1,2].

in the present research work was found to be relatively close to those reported by Tsaknis et al. [1,2].

The difference in the iodine value and other properties may be due to the quality of the oil and unfavourable environmental conditions.

Conclusion

In this present work, the extraction and characterization of *Moringa oleifera* seed obtained from Afon in Asa Local Government Area, Kwara State, Nigeria have been carried out. Although in this study, the oil yield was low, *Moringa* seeds still remain a good source for oil rich in oleic acid that could be converted to biofuel. It is a potential candidate for biodiesel production.

The *Moringa oleifera* seed oil according to Tsaknis et al. [2] could be utilized successfully as a source of edible oil for human consumption. It has been found to contain high monounsaturated fatty acids and might be an acceptable substitute for highly monounsaturated oils such as olive oil in diets.

Moringa oleifera is a tree found to thrive well even in poor soil and is not really affected by drought [5,6] and can be easily grown in developing countries like Nigeria. The extraction of oil from its seeds could be of high economic benefit to the communities where the tree is cultivated.
