Short Communication

Embryologically, anterior cerebral artery (ACA) takes a medial course in 40-day period. Anterior communicating artery develops after 4 days. Along with the development of corpus callosum, ACAs course in a frontal caudal direction [1]. ACA arises from the internal carotid artery distal to the carotid siphon, crosses the anterior perforating substance. It gives off small medial striate vessels and reaches the interhemispheric fissure and connects with the contralateral ACA by the anterior communicating artery. It then turns upward in the direction of the genu of the corpus callosum with which it is intimately associated as it parallels it in a wide arc to continue over the medial surface of the hemisphere [1]. It may occasionally lie in the cingulate sulcus. Right and left ACA vessels run in parallel. Left may possibly course slightly posterior than the right one. It supplies orbitofrontal and medial hemispheric portions of the human brain. The unusual fusion of the paired A2 is either originates from the medial branch of the olfactory artery at the initial 16 mm stage during embryonic development or the continuation of the median artery in the corpus callosum at the 24-mm stage. [2] Among the lower primates, there is no anterior communicating artery. Unpaired ACA is normal in snakes, tortoises, and crocodiles [3]. However, it is a rare variation in human in which A2 segments of both ACAs are represented by a single common vessel. It may have profound clinical implications with an incidence of 1.15 to 5% [1,2,4] which is either due to lack of development or regression of anterior cerebral artery during embryogenesis. Different types of azygos ACA has been described in the literature [4].

Type I is a classical type. All the major vessels arise from the single stump feed most of both anterior cerebral hemispheres as well as the corpus callosum (Figure 1). This is usually seen in the anterior median fissure supplying to both hemispheres. Type II has a short median stem of azygos ACA. This divides into further branches to supply both the hemispheres separately. Type III represents two separate A2 segments. Type IV shows an azygos pericallosal artery. Anterior cerebral circulation appears normal except for the pericallosal vessels. Type V has a third azygos median A2 artery. There are several variations of cerebral vasculatures. Hypoplasia, aplasia and duplications of the pre-communicating segment of ACA, duplication, and fenestration of anterior communicating artery, azygos ACA, and variation in an A2 segment of ACA in its terminal branches are among them [4]. The incidence of an aneurysm ranges from 13% to 71% in such kind of variation due to altered hemodynamics and defect in tunica media promoting the aneurysmal growth and rupture [5]. Another reason for the frequent existence of an aneurysm in the ACA is being the most primitive vessel in Circle of Willis. Arteriovenous malformation,

agenesis of corpus callosum, bilateral ischemia, holoprosencephaly, and hydranencephaly are other frequent intracranial abnormalities associated with primitive ACA [1-5].

Variation in anterior circulation poses a great surgical importance. Although fenestration, duplication or triplication has a protective mechanism for any kind of occlusion or vasospasm, however, the azygos vessel is more prone to produce grave consequences during the endovascular or surgical intervention. Although Circle of Willis has the ability for potential shunting effect during vascular compression, surgical intervention is more challenging since it may possess more risk of ischemia of both frontal lobes if the narrowing is produced. Azygos ACA with a multilobed aneurysm in Author's CT angiographic image (Figure 1) represents an archetypical picture of performing an art of ballet dance. Azygos ACA with an aneurysm pointing upward corresponds as a ballistic move. Both of her arms and the entire body has been bent backward in an arc like fashion in a single breath. Such move is made in a critical instance. Similarly, the azygos ACA carrying multiple aneurysms and feeding both anterior cerebral hemispheres in given image stands in the most life threatening condition. Therefore, clinical significance of solitary ACA is very important to consider while clipping or coiling.

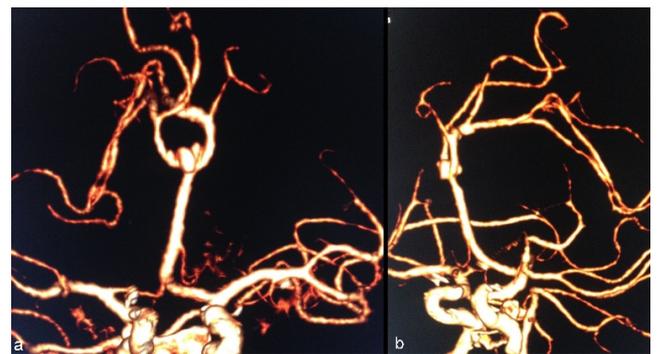

Figure 1: Major vessels arise from the single stump feed most of both anterior cerebral hemispheres as well as the corpus callosum.
