Abstract

Cholecystokinin (CCK) is a neuropeptide that affects growth rate in chickens by regulating appetite. CCK peptides exert their function by binding to two identified receptors, CCKAR and CCKBR in the GI tract and the brain, respectively, as well as in other organs. In mammals, CCK/CCKAR interactions affect a number of immunological parameters, including regulation of lymphocytes and functioning of monocytes. Thus, food intake and growth can potentially be altered by infection and the resulting inflammatory immune response. It is uncertain, however, whether chicken express CCKAR in immune organs and cells, and, if so, whether CCKAR expression is regulated by pathogen derived inflammatory stimuli. Herein, we identify expression of CCKAR protein in chicken peripheral blood mononuclear cells (PBMC) including monocytes, and expression of the CCKAR gene in PBMC, thymus, bursa, and spleen, in selected commercial and pure chicken breeds. Further, stimulation with various types of *E. coli* heat-labile enterotoxins or lipopolysaccharide significantly regulated expression of CCKAR on monocytes in the different breeds. Ligation of CCKAR with antibodies in PBMC induced mobilization of Ca²⁺, indicating that CCKAR is signal competent. Injection with polyinosinic: polycytidylic acid (poly I:C), a synthetic analogue of double stranded viral RNA that binds Toll-Like Receptor-3 (TLR3), also regulated gene expressions of CCKAR and proinflammatory cytokines, in the different breeds. Interestingly, variations in the expression levels of proinflammatory cytokines in the different breeds were highly correlated with CCKAR expression levels. Taken together, these findings indicate that the physiological function of CCKAR in the chicken is tightly regulated in immune organs and cells by external inflammatory stimuli, which in turn regulate growth. This is the first report CCKAR expression in immune organs and cells, in any species, and the initial observation that CCKAR is regulated by inflammatory stimuli associated with bacterial and viral infection.

Keywords: Appetite; CCKAR; Gangliosides; *E. coli* heat-labile enterotoxins; Immune regulation

Introduction

Cholecystokinin (CCK) is a key regulatory neuropeptide produced mainly in the upper part of the intestine by a small subset of cells during feeding. While neurons expressing agouti-related protein (AGRP) and proopiomelanocortin (POMC) in the hypothalamus are important in the control of appetite, CCK and CCK receptor (CCKR) interactions in the periphery act as a satiety feedback mechanism transmitting signals from the intestine in respect to the level of food intake [1-3]. In rodents, there are two types of CCKRs, CCKAR (also CCKR1) and CCKRB (also CCKR2) have been identified in pancreatic acini and the brain, respectively [4,5]. Whereas CCKAR is highly selective for binding a biologically active sulfated form of CCK (CCK-8), CCKBR binds sulfated, non-sulfated CCK, and gastrin [6]. Similar to the expression state in mammals, CCKRs are also expressed in various tissues in the chicken [7,8] and may perform a similar biological function. Specifically, CCKAR is widely expressed in tissues of chicken including the cerebellum, hypothalamus, small intestine, cecum, pancreas and gallbladder whereas CCKBR expression is highest in the brain and proventriculus. Recently, a region downstream the CCKAR gene and levels of CCKAR expression in nonimmune organs were implicated in variation in growth among various breeds, resulting in altered sensitivity to the CCK satiety signal [7].

While CCKAR expression was demonstrated in tissues and organs involved in food intake, control of appetite, and growth, no evidence exists in the chicken in relation to its possible distribution in immune organs and immune cells. This potential distribution is important to address since previous experiments in mammals have

shown that food intake and growth were affected by infection and the resulting inflammatory immune response, which in turn control both the biological function and the expression level of CCK [9-11]. Thus, intestinal inflammation resulted in reduced food intake that was associated with increased expression of CCK [10]. On the other hand, in the chicken, pathogens or agents that mimic pathogens components were shown to regulate expression of proinflammatory cytokines and growth, in experimentally challenged animals [11-15]. Since the expression levels of CCKAR in nonimmune organs are likely responsible for variation in growth and body weight among chicken breeds [7], CCKAR expression in immune organs would presumably provide a target for regulation of the expression by infection and/or the resulting proinflammatory cytokines.

In this study, we confirmed expression of CCKAR protein in chicken PBMC including monocytes, and revealed that CCKAR is regulated by various types of *E. coli* heat-labile enterotoxins [specifically

the B subunit of LT-I (LT-IB₅), a type I heat-labile enterotoxin, and the type II heat-labile enterotoxin LT-IIa holotoxin and its B subunit (LT-IIaB₅) [16-21], and lipopolysaccharide (LPS). CCKAR gene expression was demonstrated in various types of immune organs, and its level was regulated by poly I:C, a compound mimicking viral double stranded RNA. Poly I:C also regulated gene expression levels of proinflammatory cytokines which were highly correlated with levels of expression of CCKAR.

Materials and Methods

Chicken breeds

This study was conducted on commercial chicken strains, including Pearl White Leghorn, Red Ranger Broilers and Egyptian Fayoumi (pure breed). Birds were purchased one day old from Murray McMurray Hatchery, Iowa, USA. The chicks were a mix of males and females. Chicks were vaccinated by Marek's and Coccidia vaccines at the source. Chicks were kept in cages in the poultry house at Tuskegee University, College of Veterinary Medicine, AL, USA. Temperature in the house was maintained based on age of the bird. Starter diet and water were available ad libitum. The animal protocol was approved by Tuskegee University Animal Care and Use, and Biosafety Committees.

Reagents

Alexa Fluor 488 rabbit anti CCKAR polyclonal antibody (Bioss Inc., # bs 11514R, A488, USA) and biotin conjugated rabbit anti CCKAR polyclonal antibody (Bioss Inc., # bs 11514R, USA). The bs11514R antibodies are raised against a synthetic peptide, and are cross reactive against mouse, rat, human and chicken CCKAR. Mouse IgG FITC antibody (Southern Biotech., # 0102 02, USA), and PE conjugated mouse anti chicken monocytes/macrophages antibody (Southern Biotech., # 8420 09, USA). For calcium experiments, Fura Red, AM, cell permeant (Life Technologies, # F3021, USA), ionomycin (life technology # 124222, USA) and streptavidin from *Streptomyces avidinii* (Sigma Aldrich, # S4762, USA) were used. For cell culture, RPMI 1640 medium modified with 20 mM HEPES (Sigma # H0887, USA) and 200 mM L glutamine (Sigma # G7513, USA), penicillin/streptomycin (Sigma # P4333, USA), β-mercaptoethanol (Sigma # M6250, USA), HyClone™ fetal bovine serum (FBS) (Life Science, # SH30396.03, Canada), and Hanks' Balanced Salt Solution (Sigma # H8264, USA) were employed. For harvesting cultured PBMC, Trypsin/EDTA solution (Sigma, # T4049, USA) was used. For RNA extraction from tissue and PBMC, TRI Reagent (TRI Reagent, Sigma, # 93289, USA), and Histopaque®

1077 (Sigma, # 10771, USA) were used. For conventional PCR, Taq PCR Master Mix (2X) (QIAGEN, # 201443, USA), Gelpilot Mid-Range Ladder (100) (QIAGEN, # 239135, USA), Gelpilot® DNA loading Dye, 5x (QIAGEN, # 239901, USA) and Agarose (Biomatik, # A2127, USA). For qPCR analysis, RT2 HT First Strand Kit (QIAGEN, # 330411, USA) and RT² SYBR Green ROX qPCR Mastermix (QIAGEN, # 330520, USA), and molecular biology water (non Diethylpyrocarbonate (DEPC) treated, DNase, RNase and protease free) (Sigma# W4502) were used. For injection, poly (I:C) (InvivoGen, # tlr pic, USA) was used. For stimulation of PBMC, lipopolysaccharide (LPS) from *E. coli* 0111:B4 was purchased from Sigma Aldrich (USA). Recombinant *E. coli* heat-labile enterotoxin B subunits (LT-IB₅) expressed in the yeast *Pichia pastoris* (Sigma-Aldrich, >90% pure), and highly purified recombinants LT-IIa, and LT-IIaB₅ were used. Recombinant preparation of the B-subunits of LT-II were obtained from *E. coli* and purified to >90% by affinity chromatography using a His Bind resin column and gel filtration chromatography [22-24].

Primers

Conventional PCR primers and the β-actin primer (Table 1) were designed using Geneious R8 and Primer Blast NCBI, respectively. The amplification of the correct amplicon was confirmed by the sequence and alignment using Sequences Nucleotide BLAST NCBI. For qPCR primer assays (Table 1) were purchased from QIAGEN.

Isolation of PBMC

Blood was collected into tubes containing EDTA from the jugular vein under sterile conditions. Blood was diluted with equal volume of phosphate-buffered saline (PBS, pH 7.4) and layered onto equal volume of Histopaque® 1077. The suspension was spun down by centrifugation at 400 xg for 30 min at Room Temperature (RT). After centrifugation, the upper layer was carefully aspirated and discarded. The opaque interphase, containing PBMC, was carefully transferred with Pasteur pipette into clean sterile conical centrifuge tubes. After addition of PBS, cells were spun down for 10 min at 400 xg. The supernatant was aspirated and discarded. Washing was repeated twice before suspending the cells in PBS.

Assay for effects of toxins on PBMC

PBMC were harvested from pooled blood samples from 3 birds from each breed. PBMC (1 × 10⁶) were incubated with 5 μg/ml and 2.5 μg/ml LT-IB₅ and LT-IIaB₅, respectively. LT- IIa was used at pre-optimized dose of 100 ng; LPS was used at a concentration of 1 μg/ml. Untreated

cells (medium) were included as a control. After 24 h incubation at 37°C, the medium was removed and retained for subsequent analysis. The remaining cells were harvested from the plate by Trypsin/EDTA, and washed with PBS. To minimize unspecific binding of antibodies to cells, 1% FBS was added to cells in 200 µl PBS containing 0.5% FBS and 0.01 % NaN₃. After adding anti CCKAR antibody (1/50) and anti-monocytes KUL01 (1/400), the mixture was incubated on ice for 50 min, and analyzed by flow cytometry (Becton Dickenson, FlowJo software. Tree Star, OR). Controls included unlabeled cells and cells stained with Mouse IgG FITC antibody as a negative control for the FITC anti-CCKAR antibody.

Assay for mobilization of calcium in PBMC

PBMC from 3 broilers and 3 layers were each pooled and stimulated *in vitro* overnight with LPS to increase CCKAR expression, as shown above (Figure 1), or left unstimulated. LPS-untreated cells (medium) were included as control. To increase CCKAR expression, cells were stimulated with 1µg/ml LPS before analysis of the calcium response was performed. Cells at 5 × 10⁶/ml were loaded with pre optimized concentration of Fura Red/AM (4 µg/ml) in Hanks Balanced Salt Solution, which contains Ca²⁺, in the presence of 5% FBS. Cells and dye were incubated for 45 min at 37°C. After washing, the cells were aliquoted to 1 × 10⁶/0.5 ml buffer and rested for 30 min at RT. Cells were then pre-incubated with biotin conjugated anti-CCKAR (1/50) for 5 min at 37°C and immediately transferred to flow cytometer for analysis. A baseline measurement was obtained for the first 25 s, after which streptavidin was added at 10 µg/ml, and the acquisition continued for the total duration of 3 min. Positive and negative controls included ionomycin added at 2 µl from 3 mM reconstituted solution, and cells incubated with the antibody or streptavidin alone, respectively.

Sample collection

For tissue collection, birds of 20 day old were euthanized by terminal exposure to CO₂. For collection of PBMC, birds were bled by the heart puncture after death for RNA isolation. Tissue samples were collected from Bursa of Fabricius, thymus, and spleen. The body weight of each bird was recorded before euthanasia and collection of samples. Tissue samples were placed in 1.5 ml Eppendorf tubes, immediately frozen in liquid nitrogen, and stored at -80°C until processed in the laboratory.

RNA isolation and reverse transcription

Total RNA was extracted from 30-50 mg of tissue by the TRI reagent, pelleted and eluted in RNase free water. The integrity of the RNA was examined by gel electrophoresis and the concentration was measured by Nano drop ND1000 (NanoDrop Technologies Inc., Wilmington, USA). Two µg of RNA sample was reverse transcribed using the RT2 HT First Strand Kit. The cDNA product was verified by conventional PCR using CCKAR primers, and analyzed by agarose gel electrophoresis.

Conventional PCR

Three primers were designed to flank exon 1, 2, 3, 4, and 5 of CCKAR gene. Four µl of cDNA, 12.5 µl Taq Mastermix, 0.5 µl of forward and reverse primers (10 µM), and molecular biology water were added to a total volume of 25 µl. Thermal cycling conditions were: an initial denaturation at 95°C for 3 min, followed by 45 cycles of 95°C for 30 s, annealing for 30 s at temperature according to the primer (see above), extension at 72°C for 50 s, and final extension at 72°C for 5 min. The amplified products were examined by gel electrophoresis, sequenced, and aligned in the data base.

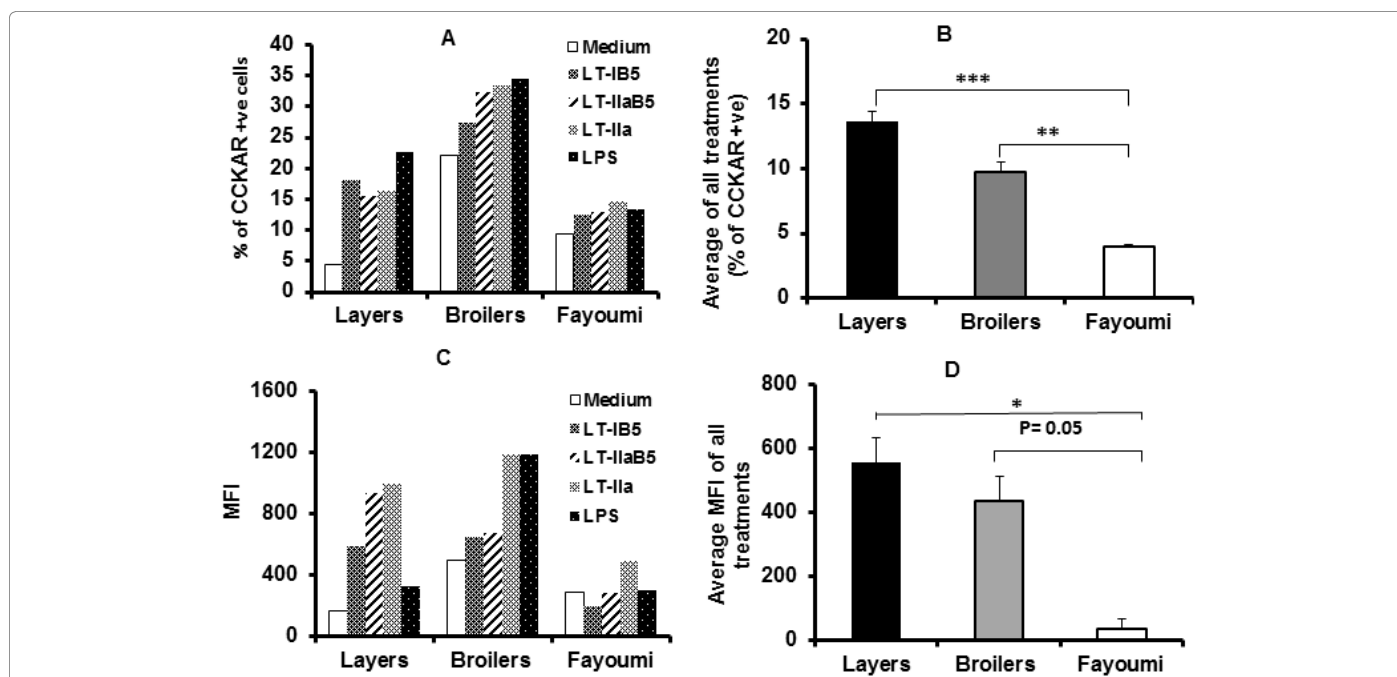

Figure 1: Stimulation of chicken monocytes significantly increases CCKAR protein expression. PBMC were cultured with the *E. coli* enterotoxin LT-IIa or the B-subunit of LT-I and LT-II (LT-IB₅ and LT-IIaB₅, respectively), or LPS. Cells were harvested, and labelled with FITC anti-CCKAR and PE anti-KUL01 (for monocytes) and analyzed by flow cytometry. The percentage of cells expressing CCKAR was determined by gating out low FSC/high SSC cells (dead cells) [17] and platelets, and by gating on CCKAR⁺ and KUL01⁺ cells. The total number of cells expression CCKAR (Figure 1A) and Mean Fluorescence Intensity (MFI) (Figure 1C) are shown. The results represent average of two experiments. In B and D, the average effects of all stimulants (- medium) on number of cells expressing CCKAR (Figure 1B) and level of CCKAR (Figure 1D) in the different breeds is compared. *, ** and *** denotes statistical significance (one-way Anova) with a p<0.05, p<0.01 and p<0.001, respectively.

Real time PCR

CCKAR, β -actin, GAPDH, IL1- β , IL-6, IFN- γ specific primers were used to amplify the gene products. For this purpose, 1 μ l of cDNA, and Real time PCR kits [RT² SYBR Green ROX qPCR Mastermix (2) (QIAGEN) were used. Amplification was carried out by using CCKAR primer assay (QIAGEN), and duplicate samples for each tissue from four birds and from each breed. Samples from two replicates were analyzed using MxPro QPCR software. The thermal cycling conditions were: initial denaturation at 95°C for 10 min, followed by 45 cycles at 95°C for 15 s, annealing/extension for 1 min at 60°C. DNA produced by Real time PCR reactions was resolved on a Stratagene 300 P Real time PCR system (Agilent Technologies, USA). Assays were analyzed using MxPro QPCR software (Agilent Technologies, USA). CT values for each sample were determined and used in the calculation of "fold change" based on the Livac method [25], mRNA expressions for each tissue were normalized using β actin and GAPDH.

Poly I:C injection and its effects on CCKAR and cytokines gene expression levels

20 days old birds were injected with poly I:C (100 μ g/kg bwt). 10 birds from each breed, were injected IP with Poly I:C (100 μ g/kg bw). Four additional birds from each breed were injected with PBS (controls). Tissue samples were collected after 24 h from all organs. Total RNA was extracted and Real time PCR analysis was performed as described above.

Statistical analysis

Statistical analysis of the data was performed using GraphPad Prism 6 software (GraphPad software Inc.). One-way ANOVA was used to examine the breed effect on CCKAR expression. Two-way ANOVA was used to examine the breed and organ effects on CCKAR expression. For statistical significance between breeds, one-way ANOVA was followed by the unpaired t-test, and two-way ANOVA was followed by the Holm Sidak method. Linear regression analysis was performed to determine the association between expressions of CCKAR and cytokines.

Results

Stimulation of chicken PBMC by toxins significantly increases CCKAR protein expression

CCK/CCKAR interactions in mammals or their derived cells have been shown to affect a number of immunological parameters, including regulation of lymphocytes and monocytes function [26-28]. However, there is no evidence in chicken how CCKAR expression is regulated by external stimuli including infectious agents and their products. Since the immune response, particularly the inflammatory response to infectious agents may have dramatic consequences on appetite and growth we examined the effect of a set of bacterial toxins on protein expression of the CCKA receptor in PBMC and on the surface of monocytes in different breeds of chicken.

Figure 1 shows CCKAR expression in unstimulated (medium) and stimulated PBMCs. Following stimulation with LPS, LT-IB₅, LT-IIaB₅, and LT-IIa, for 24 h at 37°C, cells were labelled with FITC anti CCKAR and the chicken monocyte/macrophage KUL01 Abs, and analyzed by flow cytometry. The data in Figure 1A is showing the percentage of treated PBMC including monocytes expressing CCKAR. CCKAR expression increased in all breeds compared to cells incubated with the medium alone. However, the noticeable increase in CCKAR expression is shown in the commercial layers and broilers compared to the pure

breed Fayoumi, when treated and untreated cells were compared. For statistical analysis and to minimize bias effects of one treatment, the added effects of all inflammatory mediators (minus medium) were calculated (Figure 1B). This was statistically highly significant in the formers (One-way ANOVA, $p=0.01$ for broilers and $p=0.001$ for layers) compared to the Fayoumi breed. A representative contour double staining analysis of the cells from one experiment is shown (Figure 1 supplement). As shown, compared to medium, the toxins and especially LPS increased the number of cells expressing CCKAR in PBMC. Further, LPS had notable stimulation effect on monocytes in layers and broilers but no effect in the Fayoumi.

Because the effects of the holotoxin, B subunits and LPS could also result in an increase in the level (rather than number) of CCKAR on cells that already express detectable amount of the receptor, we performed histogram analysis of the data in which traces of stimulated and unstimulated cells were superimposed. An increase in the mean fluorescence intensity was then recorded. The overall effect in Figures 1C and 1D show similar patterns to those in Figures 1A and 1B, noticeably an increase in the level of CCKAR in the commercial breeds compared to Fayoumi. The added effects of PBMC stimulation by all bacterial toxins (minus medium) was also statistically significant or nearly significant in the formers (One-way ANOVA, $p=0.02$ for layers and $p=0.05$ for broilers).

Chicken CCKAR is a signaling competent receptor on PBMC

To ensure that CCKAR on PBMC is functional, the ability of anti CCKAR antibody to induce mobilization of calcium was investigated (Figure 2). Calcium ions (Ca^{2+}) are universal intracellular messengers that control a variety of different physiological processes in the cells such as neurotransmitters release, muscle contraction, cell proliferation, gene transcription, etc. [29-31]. In immune cells, elevation of calcium is generally an indication of cell activation.

The capacity of the cells to flux Ca^{2+} was initially evaluated by adding ionomycin, an effective ionophore that raises intracellular Ca^{2+} levels (insert in Figure 1). Cells stimulated with LPS in the absence of anti CCKAR ab were taken as a base level of fluorescence (Figure 2).

Figure 2: Mobilization of Ca^{2+} following ligation of CCKAR. PBMC were isolated from pooled blood samples from 3 birds. To stimulate expression of CCKAR, cells were pre cultured for 24 h with LPS. Cells were then loaded with Fura Red Ca^{2+} dye. To induce mobilization of calcium, biotin conjugated anti CCKAR antibody and streptavidin were employed. Shown is a representative of one of two experiments with similar results. LPS indicates cells stimulated with LPS alone (no anti CCKAR); anti CCKAR indicates non LPS stimulated cells ligated with anti CCKAR + streptavidin; LPS + anti CCKAR ab indicates LPS stimulated cells ligated with anti CCKAR antibody + streptavidin, and streptavidin indicates cells to which streptavidin alone was added.

Ligation of LPS-stimulated cells with anti CCKAR antibody followed by streptavidin induced mobilization of Ca^{2+} (decrease in fluorescence is a property of Fura Red in loaded cells with the dye). However, even in the absence of prior LPS stimulation, ligation of CCKAR by the antibody and streptavidin induced a similar decrease in the level of fluorescence. Addition of streptavidin alone or anti CCKAR antibody without ligation with streptavidin did not induce mobilization of calcium. These results demonstrate that anti CCKAR antibody induces mobilization of Ca^{2+} in chicken PBMC suggesting that chicken CCKAR is signaling competent.

Chicken CCKAR is expressed in immune organs and PBMC in different breeds

Having demonstrated CCKAR protein expression on monocytes and PBMC, mRNA gene expression was then examined in PBMC and in several immune organs including the bursa, thymus, and spleen. Since maturation of the bursa and its maximum size occurs between 2 to 4 weeks after hatching, an event that is also mimicked by the development of the thymus, conventional PCR followed by Real time PCR analysis of CCKAR gene expression were performed in 20 days old chicks from each breed. Conventional PCR (Figure 3 supplementary material) was performed as an initial screening for CCKAR gene expression in chicken immune organs before qPCR analysis. RNA was extracted from different tissues and from PBMC and reverse transcribed into cDNA. This was further used in PCR and real time PCR. For each procedure, specific primers were used for amplification (Table 1).

Amplification of CCKAR gene in PBMC, spleen, bursa and thymus in tissues and cells isolated from the layers are shown (Figure 3, supplementary material). A similar DNA profile was obtained from a transcript analysis of the other two breeds (data not shown). The product size from Exon 1 was 559 bp; Exon 2, 3 and 4 sizes were 417 bp, and Exon 5 size was 413 bp. The amplicons were subsequently sequenced and aligned on the database to the CCKAR gene sequence. An alignment match of 99% was present. This is the first report that demonstrates the presence of the CCKAR gene message in chicken PBMC, bursa, spleen and thymus.

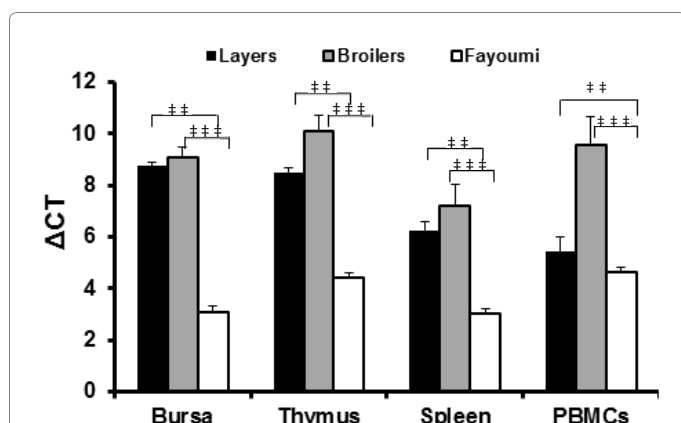

Figure 3: Expression of CCKAR message in immune organs and PBMC. RNA was extracted from different tissues and from PBMC from four 20 day old birds, and reverse transcribed to cDNA. Amplification was performed using Real time PCR system. Shown are averages \pm SEM of Δ CT values from 4 birds for each breed, calculated by determining the CT value of CCKAR compared to that of the house keeping gene, β actin. Two-way ANOVA followed by two tailed unpaired t-test were used to determine the statistical analysis. ** and *** denotes significance with $p < 0.01$ and $p < 0.001$, respectively.

To address expression level of the CCKAR gene, Real time PCR was performed, and levels were compared in different breeds (Figure 3). While differences in CCKAR expression in PBMC and the immune organs were not statistically significant between broilers and layers, expression was significantly higher in Fayoumi compared to the other breeds (Two-way ANOVA, $p < 0.01$ and $p < 0.001$ compared to layers and broilers, respectively). This is shown by the significantly lower value of Δ CT (Figure 3). There was no effect of the organs on CCKAR expression in the different breeds (Two-way ANOVA, $p > 0.05$). These results demonstrated that CCKAR was expressed in multiple immune organs and in PBMC, and that the levels of expression varied among breeds.

Poly I:C injection regulates CCKAR and cytokines gene expressions in immune organs and PBMC

Inflammatory mediators such as bacterial toxins can influence expression of CCKAR (Figure 1). We further examined how poly I:C, a synthetic analogue of double stranded RNA, that binds TLR3 and induce production of proinflammatory cytokines, regulates CCKAR and cytokines gene expressions in immune organs and in PBMC (Figure 4). Twenty day old chicks were injected with 100 μ g/kg bwt of poly I:C. Control birds were injected with PBS only. RNA was extracted from the different tissues and from PBMC and reverse transcribed. Real time PCR was performed in samples containing cDNA from each tissue.

The injection of poly:I:C increased the level of expression of CCKAR in all immune organs in the broilers and layers chicks, whereas a decrease in expression was noticeable in all organs in the Fayoumi with the exception of the spleen in an increase occurred. The breeds and the organs effects on the level of CCKAR expression were statistically significant (Two-way ANOVA, for breeds $p < 0.0001$; for organs $p < 0.05$). There was also significant effect of the interactions between organs and breeds on CCKAR expression ($p < 0.05$). The difference in CCKAR expression levels between layers and Fayoumi were statistically significant in the bursa, thymus and PBMC, but not in the spleen (Two-way ANOVA, $p < 0.001$ for the bursa and thymus, and $p < 0.01$ for PBMC) (Figure 4A). Further, the difference in the expression level between broilers and Fayoumi were statistically significant in the spleen, thymus and PBMC, but not in the bursa (Two-way ANOVA, $p < 0.001$ for thymus and PBMC, and $p < 0.05$ for spleen). Finally, CCKAR expression level was significantly different in the broilers compared to the layers, but only in the spleen ($p < 0.05$). Thus poly I:C injection differentially regulated CCKAR expression in the different breeds; it downregulated expression in Fayoumi, in the bursa, thymus and PBMC, while it increased expression level in the layers and broilers in these organs. In the spleen, however, poly I:C increased the expression of CCKAR in all breeds.

To determine if expression of CCKAR was correlated with expression of inflammatory cytokines, we also measured the expression of IL-1 β , IL-6 and IFN- γ in various tissues in the different breeds. Figure 4B shows effects of poly I:C injection on the expression level of inflammatory cytokines in the different immune organs, and for each breed. Because there is no reported known function of inflammatory cytokines in the thymus, this organ was not analyzed.

For IL-1 β , there was significant effect of the breed, the organs, and both on this cytokine (two-way ANOVA, $p < 0.05$ for the breed; $p < 0.0001$ for the organs; $p < 0.0001$ for both). Analysis of IL-1 β expression in the bursa revealed significantly higher expressions in Fayoumi compared to layers and broilers (Two-way ANOVA, $p < 0.001$ compared to layers and $p < 0.05$ compared to broilers). On the other hand, in the spleen, IL-1 β

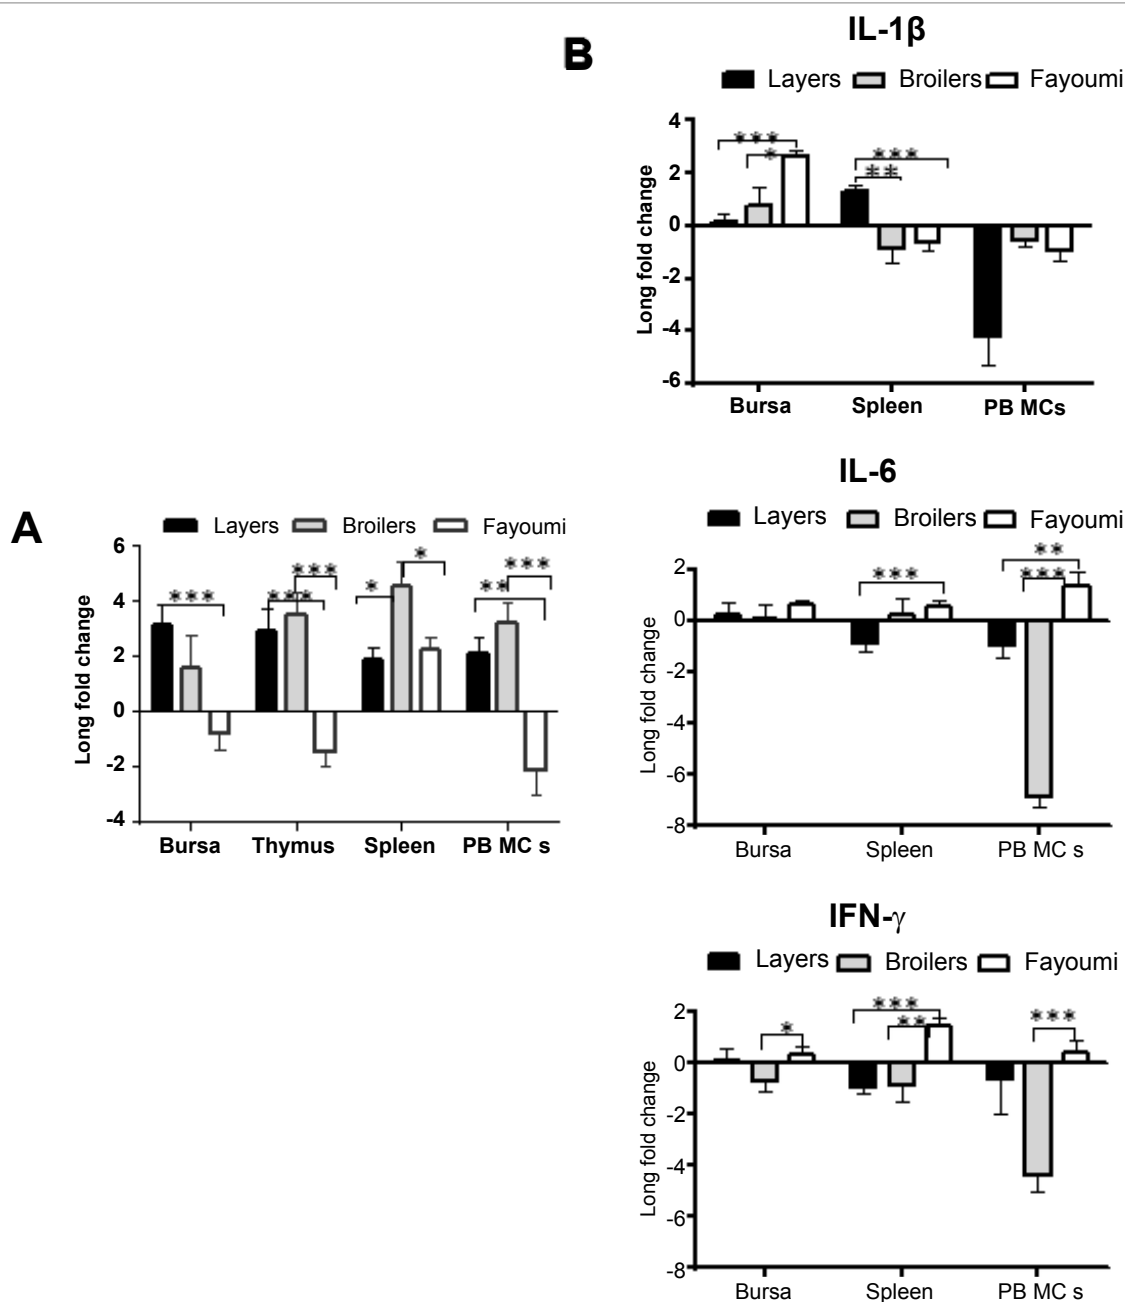

Figure 4: Poly I:C injection regulates CCKAR and cytokines gene expressions in Immune Organs and PBMC. RNAs from different tissues were extracted and reverse transcribed to cDNA. The cDNA was used to analyze gene expression by Real time PCR. In A: Log 2 fold change of CCKAR gene expression after poly I:C injection is shown. In B: Log 2 fold change of cytokines gene expression after poly I:C injection is shown. Two-way ANOVA was used to test the effect of breeds, organs, and both on CCKAR and cytokines. For comparative analysis of significance between breeds two-way ANOVA was followed by the Holm Sidak method. *, ** and *** denotes significance with $p < 0.05$, $p < 0.01$ and $p < 0.001$, respectively. Shown are the averages of log 2 fold change in birds +/- SEM.

was downregulated in the broilers and Fayoumi while it was significantly increased in the layers ($p < 0.001$ and $p < 0.01$ compared to Fayoumi and broilers, respectively). In PBMC, IL-1 β was downregulated in all breeds. Thus, in Fayoumi poly I:C injection significantly increased expression of IL-1 β in the bursa, and downregulated the expression in the spleen and PBMC. Further, with the exception of a significant increase of IL-1 β expression in the spleen, in the layers, expression levels in the bursa and PBMC in the layers and broilers were either not significant or are downregulated.

For IL-6, there was significant effect of the breed, the organs, and both on this cytokine (two-way ANOVA, $p < 0.0001$ for each). Poly I:C injection increased its expression in the bursa in all breeds. However, this was not significantly different among the breeds. Further, poly I:C downregulated IL-6 expression in the spleen in the layers whereas its expression was significantly higher in Fayoumi compared to layers ($p < 0.001$). In PBMC, poly I:C injection downregulated expression of IL-6 in the broilers and layers whereas in Fayoumi this was significantly higher ($p < 0.001$ and $p < 0.01$, respectively). Thus, in Fayoumi poly I:C increased

expression of IL-6 in the bursa, spleen and PBMC. On the other hand, in the layers and broilers, the expressions were downregulated or were not significant, except in the bursa where IL-6 expression is increased.

For IFN- γ , there was significant effect of the breed, the organs, and both on this cytokine (two-way ANOVA, $p < 0.0001$ for the breed; $p < 0.01$ for the organs; $p < 0.01$ for both). The general trend was little or downregulation of the expression in the layers and the broilers while IFN- γ expression was significantly higher in Fayoumi in the bursa, spleen and PBMC compared to broilers ($p < 0.05$ in the bursa, $p < 0.05$ and $p < 0.01$ in the spleen, and $p < 0.001$ in the PBMC). IFN- γ expression in the Fayoumi was also significantly higher compared to the layers, but only in the spleen ($p < 0.001$).

In conclusion, poly I:C injection regulated, though variably in different breeds, expression levels of CCKAR and inflammatory cytokines in immune organs. Nevertheless, most of the increases in cytokines expression occurred in Fayoumi while CCKAR expression level in this breed decreased. A similar inverse relationship trend may be applied to the layers and broilers wherein no significant effect, or a decrease in cytokines expression levels, was associated with an increase of those of CCKAR.

Variations in the expression levels of inflammatory cytokines are predicted from those of CCKAR in immune organs

To better visualize the directions of CCKAR and cytokines

expressions in the bursa, spleen and PBMC, in each breed, a summary graph depicted from Figure 4 is shown (Figure 5A).

For linear regression analysis of the expressions (Figure 5B), the question posed in the test was “what would best predict variations in the level of each or combination of the cytokines from CCKAR expression levels in each organ following poly I:C injection?”. The r^2 value, a measurement of the linear relationship between these 2 parameters, and the p value set at 90% confidence level, are reported.

In the layers, a significant association was found between the level of CCKAR expression with each of those of the IL-6 and IFN- γ in PBMC ($p < 0.1$, and $p < 0.001$, respectively). Additionally, a significant association occurred when the added effects of multiple cytokines was analyzed. Thus, CCKAR expression level was associated with IL-1 β +IL-6, IL-1 β +IFN- γ , and with all 3 cytokines, in the bursa ($p < 0.1$, $p < 0.1$ and $p = 0.05$, respectively). In PBMC, CCKAR expression level was also associated with the combined levels of the 3 cytokines ($p < 0.01$).

In the broilers, a significant association was only found in the bursa. In this case, the trend of CCKAR gene expression was associated with IL-1 β , IL-1 β +IL-6, IL-1 β +IFN- γ , IL-6+IFN- γ and with all 3 cytokines ($p < 0.01$, $p < 0.01$, $p < 0.01$, $p < 0.1$, and $p < 0.01$, respectively).

In the Fayoumi, an association between CCKAR and cytokines expression levels was found only in the spleen and PBMC. In the spleen, this was significant for each of IL-1 β and IFN- γ ($p = 0.1$ and

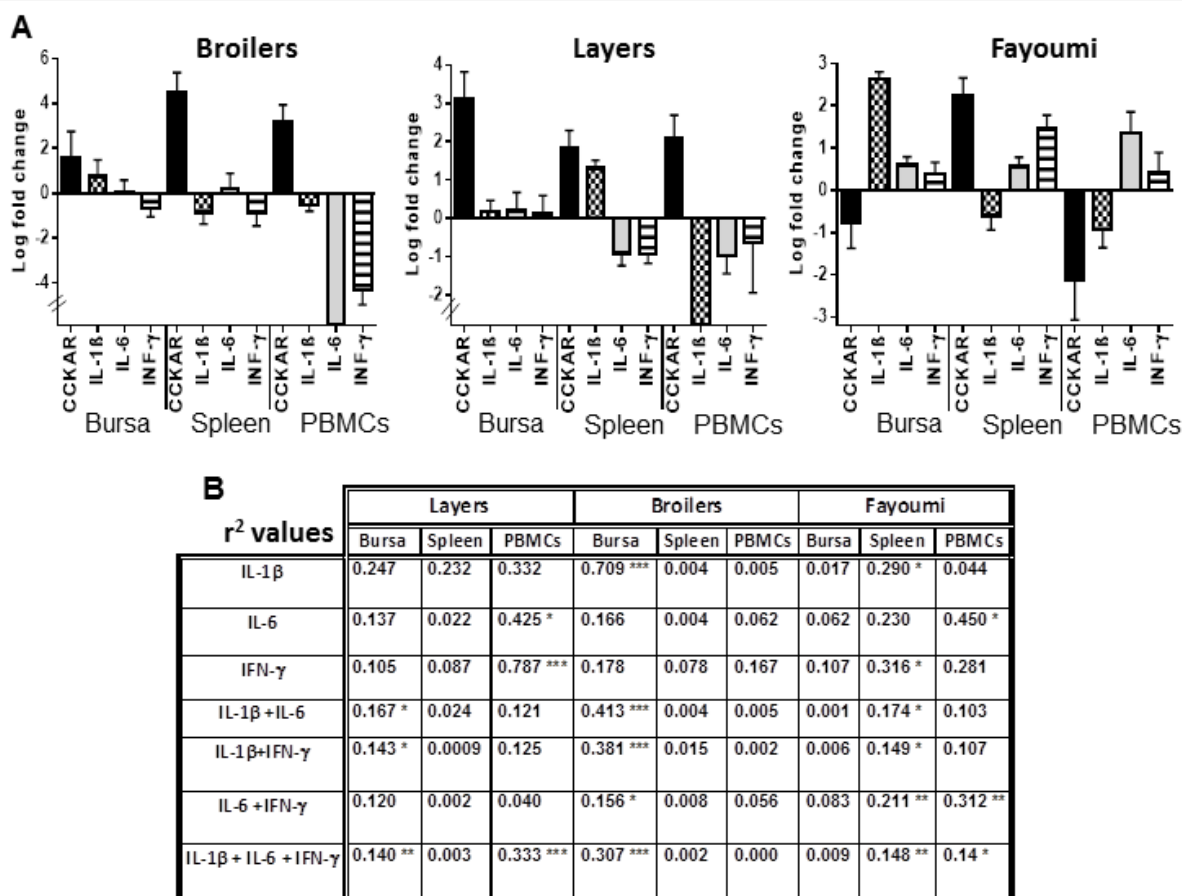

Figure 5: Variations in the expression levels of inflammatory cytokines are predicted from those of CCKAR in immune organs. A: summary of the effect of poly I:C injection on CCKAR and cytokines gene expression in the different breeds. B: regression analysis of the association between CCKAR and cytokines gene expressions. Analysis was performed at 90% confidence level. Shown are the r^2 values. *, **, and *** denote statistical significance at $p < 0.1$, $p < 0.05$ and $p < 0.01$, respectively.

$p < 0.1$, respectively); IL-1 β +I-6 ($p < 0.1$); IL-1 β +IFN- γ ($p < 0.1$); IL-6+IFN- γ ($p < 0.05$); and with all 3 cytokines ($p < 0.01$). On the other hand, in PBMC, a significant association was found with IL-6 ($p = 0.1$); IL-6+IFN- γ ($p < 0.05$); and all 3 cytokines ($p < 0.1$).

In summary, expression levels of inflammatory cytokines could be predicted from the levels of CCKAR expressed in immune organs and PBMC. Noteworthy, the strongest association between these 2 parameters in all breeds was evident in the combined expressions of IL-1 β +IL-6+IFN- γ . Nevertheless, good associations could also be found with single cytokines or a mix of 2 cytokines. It should be noted that a similar regression analysis in which cytokines were chosen as a fixed parameter with variable CCKAR expression levels resulted in a similar linear relationship (not shown). These results support statistically significant association between expression of CCKAR and the proinflammatory cytokines, following poly I:C injection.

Discussion

In this paper, we postulated that CCKAR expression in the chicken extends beyond organs directly involved in the control of appetite and growth, and includes immune organs and cells. We moreover hypothesized that external pathogen derived stimuli and endogenous cytokines regulate CCKAR expression level. These notions were confirmed by our data. We demonstrate that CCKAR protein is expressed in PBMC and is a competent signaling receptor. Further, inflammatory stimuli such as bacterial toxins and LPS, and poly I:C, regulate CCKAR protein level, and its message is detected in PBMC, spleen, bursa, and thymus, respectively. Moreover, poly I:C regulates expression of proinflammatory cytokines in those organs in the different breeds examined. Finally, an association between expression levels of CCKAR and those of cytokines is demonstrated.

A large number of studies in mammalian species addressed the role of CCK in mediating satiety signal feedback in unchallenged animals. Moreover, the effects of pathogens and inflammatory agents on CCK level, food intake, and growth have also been examined. Thus, CCK had pleiotropic effects on mammalian immune cells, including suppression of B cell costimulatory molecules, maturation of dendritic cells, murine macrophages, human neutrophils, and proinflammatory cytokines [10,28,32-35]. These studies highlighted the crosstalk between pathogens, CCK, and the immune system.

In the chicken, on the other hand, there is a lack of understanding of the mechanisms involved in the crosstalk between CCK, pathogens and the immune response [14,36,37]. Because the expression level of CCKAR on various cells could affect the physiological function of CCK and its outcome, studies that investigate CCKAR expression in challenged and unchallenged animals would be of great importance. Recently [7], addressed the role of a region downstream the CCKAR gene, and levels of CCKAR expression in nonimmune organs. These were reported responsible for variations in growth among chicken strains, resulting in altered sensitivity to the CCK satiety signal. Thus, by using 16 generations of cross between fast and slow growing strains of chicken, a region downstream the CCKAR gene was responsible for up to 19% difference in body weight. Moreover, when levels of CCKAR mRNA were measured after injection of CCK, these were lower in the high growth compared to the low growth strains whereas it was intermediate in the heterozygotes. These results have been interpreted in light of the modern changes in appetite introduced in the domestication of chicken.

To address the possible crosstalk between pathogen derived stimuli,

CCKAR, and cytokines, we selected 3 breeds that represent high growth broilers (Red Ranger Broilers), relatively low growth layers (Pearl White Leghorn) and a pure breed (Egyptian Fayoumi). The pure breed Egyptian Fayoumi is generally well known for its resistance to disease [38,39], as such would be ideal to compare the effects of those stimuli on CCKAR expression levels in this breed with the other two breeds. Figure 1 shows comparative CCKAR protein expression data of the 3 breeds as a result of stimulation of PBMC with various forms of *E. coli* - labile enterotoxins and LPS. In this regard, LT-IIa, LT-IIaB₅, and LT-IB₅ bind to ganglioside receptors expressed on surface of immune cells, and induce signals resulting in activation of antigen presenting cells (including monocytes), T cells, and secretion of cytokines [16-21]. The results in Figure 1 clearly show a striking difference in CCKAR protein expression among the different breeds after stimulation. The most notable is the significantly lower expression of the receptor in Fayoumi compared to the other 2 breeds. Considering that LT-IB₅, LT-IIa, LT-IIaB₅, and LPS each binds to a different receptor; GM1, GD1b, a complex of GD1b and TLR2, and TLR4, respectively [16,20,22], this result is a strong indication of CCKAR low expression and unresponsiveness to these bacterial stimuli in the Fayoumi birds. Conversely, in the broilers and layers, signaling pathways involved in the response to LPS and the enterotoxins appear to intersect with those involved in the upregulation of CCKAR. CCKAR is a G protein-coupled 7-transmembrane spanning receptor. Further experiments addressed CCKAR signaling competence in PBMC (Figure 2). Ligation of CCKAR with specific antibody induced mobilization of calcium. This result is consistent with those in the mammalian counterpart where CCKAR signals involved a number of pathways that ultimately generate calcium, NF- κ B and PKC [6].

Having demonstrated CCKAR protein expression in PBMC, we hypothesized that CCKAR is expressed in immune organs such as the spleen, bursa and thymus, as well as in PBMC. The data from Figure 3, using both PCR and Real time PCR, demonstrated the presence of the gene message in those organs and in PBMC. CCKAR normal expression in the Fayoumi birds was significantly lower compared to the broilers and layers, consistent with its protein expression, at least in monocytes in PBMC (Figure 1). In this regard, the expression of receptors other than CCKAR on immune cells which are involved in the control of food intake at the hypothalamic level is documented in mammals. For example, a previous report indicated that immune cells expressed leptin and ghrelin receptors on human T lymphocytes and monocytes by which they exert mutually antagonistic effects on the secretion of proinflammatory cytokines [40]. Similarly, in a mouse model of induced inflammation, CCKAR antagonist restored food intake that was dependent on CD4⁺ T cells and IL-4R α [10].

Further indication of the influence of agents that produce proinflammatory cytokines on CCKAR expression is shown in Figure 4 and Figure 5. Poly I:C is a synthetic analogue of double stranded viral RNA that binds TLR3, and induce chicken proinflammatory cytokines including IL-1 β , IL-6, and type 1 IFN- γ [41,42]. Poly I:C was also reported to act synergistically with CpG-ODN (binds to TLR21 the avian equivalent to mammalian TLR9) to increase the production of NO and expression of inducible nitric oxide synthase [41] and the magnitude of IFN- γ and IL-10 mRNA [43]. These results indicated that CpG-ODN and poly I:C synergize to promote a Th1-biased inflammatory. Further, the synergistic effects of CPG-ODN and poly I:C was evident in stimulation of IL-4 and IL-10 suggesting a feedback mechanism to the inflammatory Th1 response to these agonists [43]. Nevertheless, stimulation by each of these agonists alone resulted in differential outcomes of cytokines expression [43].

In the current study; however, it was unclear whether the injection of poly I:C regulated other factors which may be implicated in the increase of CCKAR expression. One possibility is that poly I:C induced expression of proinflammatory cytokines that acted on cells expressing CCKAR. Analysis of the expressions of IL-1 β , IL-6 and IFN- γ revealed that most of the increases in cytokine expressions appeared to occur in the Fayoumi birds, while at the same time CCKAR expressions decreased in those shown organs (Figure 4B). Nevertheless, in the Fayoumi in the spleen CCKAR expression increased and IL-1 β decreased. Similarly, in PBMCs, CCKAR expression decreased while IL-1 β expression decreased. The increase in proinflammatory cytokines concomitant with a decrease in CCKAR expression in this breed may be responsible for its reported resistance to disease [38,39,44], and is consistent with the CCK inhibitory function in mammalian immune cells [10,11,34]. A similar inverse trend between CCKAR expression and those of some proinflammatory cytokines is shown for the layers and broilers (Figure 5A). However, in this case, except for IL-1 in the spleen, the increases in the level of cytokines were either minimal or their levels were downregulated suggesting the possibility that these two breeds are less able to fight some pathogen insults, represented here by poly I:C, compared to the pure Fayoumi breed. Moreover, the presence of an association between CCKAR expression levels and those of proinflammatory cytokines following poly I:C injection (Figure 5B) suggests their mutual regulation.

Analysis of the effects of organs on normal CCKAR expression showed no statistical significance (Figure 3B) whereas after injection of poly I:C both the breed and organs had significant effects on the levels of expression of CCKAR and cytokines (Figure 4). Although there was a variation in how each of the immune organs and breeds influenced the level of expression, nevertheless this study highlights the importance of the breed and immune organ in considering future challenge experiments that address chicken growth. For example, areas of future investigation will be the type and role of cells that express CCKAR in determining outcome of cytokine expression in these organs, and whether CCKAR expression affects expression of other cytokines that may play an important role in stimulating chicken growth or their immunity against microbial challenge. Moreover, similar investigation of CCKAR expression in immune organs in other species may point out to evolutionary conservative traits.

In conclusion, the results in this study demonstrate expression of CCKAR in immune organs and cells in a variety of selected breeds of chicken. CCKAR in PBMC, and presumably in the spleen, bursa and thymus, is signaling-competent. CCKAR is regulated in these organs by the selected external bacterial and viral stimuli. Further, the association between CCKAR and proinflammatory cytokines suggests that CCKAR expression is tightly regulated by these pathogen stimuli. The sensitivity of CCKAR expression appears to vary among the different chicken breeds. The results implicate the involvement of immune organs in the regulation of CCKAR expression by agents that induce proinflammatory cytokines.
