Abstract

Fruit of date palm (*Phoenix sylvestris* L.) is edible and used as an anti-geriatric, anti-oxidant ethnomedicine. In this study, three different types of date palm extracts, methanolic, acidic ethanolic and basic ethanolic were evaluated for their putative in vitro scavenging effects on reactive oxygen species (ROS) where scavenging of hydroxyl radicals (basic ethanolic>acidic ethanolic>methanolic), superoxide radicals (acidic ethanolic>basic ethanolic>methanolic), DPPH radical (acidic ethanolic>methanolic>basic ethanolic), [nitric oxide (NO)] (methanolic>acidic ethanolic>basic ethanolic) and inhibition of lipid peroxidation (basic ethanolic>acidic ethanolic> methanolic) were found to occur in a dose dependent manner. Their flavonoid and phenolic contents proved to be the source of this potent scavenging activity and showed a direct correlation with their total anti-oxidant capacity. On human embryonic kidney cell line (HEK) and murine RAW macrophages, bacterial lipopolysaccharide (LPS) induced inflammation, the date palm extracts applied therapeutically, inhibit intracellular oxidative stress significantly. This reinstatement of cellular homeostasis presumably occurs via mitochondrial pathways.

Keywords: Inflammation; Anti-oxidant; Phenolic compounds; Scavenger activities; Reactive oxygen nitrogen intermediates

Introduction

Inflammation, either acute or chronic, is the body’s response to disturbed homeostasis caused by infection, injury or trauma resulting in systemic and local effects. Inflammatory response occurs in three distinct phases [1]. The first phase is caused by an increase in vascular permeability resulting in exudation of fluids from the blood into the interstitial space, the second phase involves the infiltration of leukocytes from blood into tissue space and in third phase granuloma formation and tissue repair occurs.

Inflammation is the key driving force for most disorders. A delicate balance between beneficial effects of inflammation cascades and their apparently destructive mechanism is key to the body’s homeostasis and it is the breakdown of such balance through regulatory disruption that lead to the clinical manifestation of diseases such as asthma, rheumatoid arthritis, psoriasis, multiple sclerosis, obesity and inflammatory bowel disease [2]. Though the specific characteristic features of inflammatory response in each disease and the site of their occurrence may vary, a universal feature governing this phenomenon is the complex interplay amongst the many different inflammatory cell types, recruitment and activation of inflammatory cells such as neutrophils, eosinophils and macrophages and changes in the structural cells with a concomitant increase in the expression of components of inflammatory cascade including cytokines, chemokines, growth factors, enzymes, receptors, adhesion molecules and other biochemical mediators, affecting various target tissues [2,3].

Despite the advances in medical technology and hygiene, the introduction of vaccines and modern medications, and intense ongoing research, the prevalence of inflammatory disorders has continued to increase in the last few decades throughout the globe [4]. Although the best approach to investigate various inflammatory processes, and to identify crucial pathways and potential novel targets for drug therapy, is to perform studies in human patients, due to ethical reasons these are not always possible necessitating the development of various preclinical animal models and cell lines, both human and non-human, to elucidate the pathophysiology of various inflammatory disorders, and to identify and evaluate novel therapeutic targets for them. The utility of these models, both *in vitro* and *in vivo*, to understand the mechanistic phenomenon operative in a human disease and to develop therapeutics, is the topic of considerable debate due to the non-availability of any completely accepted model for the human disease. Preclinical disease models need to be carefully selected if they are to be predictive of the biology, expected in treating human disease. Consideration of the particular biology reflected in the model, as well as whether the qualities of the potential therapeutic (or its species-specific surrogate molecule) will be represented adequately in a non-human species, so that the drug discovery and development industry will continue to make progress in predicting potential therapeutic efficacy and benefit of new drugs in patients for the successful drug development.

From the ancient period the role of traditional medicines in the solution of health problems is invaluable on a global level. In traditional medicine medicinal plants continue to provide valuable therapeutic agents. Due to various side effects and complications of the modern medicine, and to address unmet needs of the particular disease, specially complex etio-pathophysiological pathways traditional medicine is gaining importance and is now being studied systematically and using biotechnological tools, to find the scientific basis of their therapeutic actions.

Phytochemicals from fruits and other edible plant parts have been shown to possess significant antioxidant properties that may be associated with lower incidence and lower mortality rates of degenerative diseases in human. Different biological properties, antioxidant capacities and radical-scavenging activities of various herbal extracts have been widely demonstrated, using *in vitro* techniques and *in vivo* models by different groups of researchers [5-7]. The anti-proliferative and anti-inflammatory activities of these herbal
extracts have been documented in human oral, breast, colon, cervical, and prostate cancer cell lines as well as preclinical animal models by attenuating some inflammation intermediates, including nitric oxide, NF-κB, and TNFα [8,9].

The aim of our study was to first detect potential anti-inflammatory activities of various extracts from a fruit that is traditionally known as an anti-geriatric compound. High content of various phenolic and non-phenolic compounds and other uncharacterized moieties may contribute to its use not only as a highly nutritive edible plant part but also position it as a nutraceutical substance and a prophylactic cum therapeutic compound in oxidative inflammatory diseases. Comparison of antioxidant and anti-inflammatory activities of date palm extracted by three distinct methods viz. methanolic extracts, basic ethanolic extracts and acidic ethanolic extracts have been assessed along with evaluation of their anti-oxidative / anti-inflammatory capacities.

### Materials and Methods

#### Reagents

Chemicals, such as ethylenediamine tetra acetic acid (EDTA), trichloroacetic acid (TCA), butanol, ammonium molybdate, and sodium dodecyl sulphate, benzoic acid, sodium phosphate, DMSO were purchased from E. Merck (India) Limited. 1,1 Diphenyl-2-picrylhydrazyl and Malondialdehyde, Potassium ferricyanite, thiobarbituric acid (TBA) were procured from Sigma, USA. N-butanol, Furu sulphate, Ferric chloride, Folins reagent, Riboflavin, naphthylethyleneimine dihydrochloride, and sulphanilamide in phosphoric acid, Sodium bicarbonate, Sodium hydroxide, and potassium hydroxide were purchased from Sisco Research Laboratories Pvt. Ltd India. Nitroblue tetrazolium, were purchased from Himedia, India. All other reagents were of analytical grade.

#### DPPH radical-scavenging activity

The antioxidant activity of the extracts was measured on the basis of the scavenging activity of the stable 1,1-diphenyl-2-picrylhydrazyl (DPPH) free radical [10]. Aqueous extract was added to a 0.004% Methanol solution of DPPH on a 96 well ELISA plate. Absorbance at 517 nm was determined after 30 min, and the percent inhibition activity was calculated.

#### Assay of superoxide radical O$_2^-$ scavenging activity

The method used by Martinez et al. [11] for determination of the superoxide dismutase was studied in the riboflavin-light-nitroblue tetrazolium (NBT) system [12]. Each 0.1 ml of reaction mixture contained 50 mM phosphate buffer (pH 7.8), 13 mM methionine, 21 M riboflavin, 100 μM EDTA, NBT (75 μM) and various doses of sample solution. The production of blue formazan was followed by monitoring the increase in absorbance at 560 nm after 15 min of illumination from a fluorescent lamp.

#### Assay of hydroxyl radical (-OH)-scavenging activity

The assay was based on the benzoic acid hydroxylation method [13]. Hydroxyl radicals were generated by direct addition of iron (II) salts to a reaction mixture containing phosphate buffer. In a 24 well plate, 0.15 ml of sodium benzoate (10 mM) and 0.15 ml of FeSO$_4$, 7H$_2$O (10 mM) and EDTA (10 mM) were added. Then the sample solution and a phosphate buffer (pH 7.4, 0.1 M) were added to give a total volume of 1.6 ml. Finally, 0.15 ml of an H$_2$O$_2$ solution (10 mM) was added. The reaction mixture was then incubated at 37°C for 2 h. After that, the fluorescence was measured at 407 nm emission (Em) and excitation (Ex) at 305 nm. Measurement of spectrofluorometric changes has been used to detect the damage by the hydroxyl radical.

### Lipid peroxidation assay

A modified thiobarbituric acid reactive species (TBARS) assay was used to measure the lipid peroxide formed using egg yolk homogenates as lipid-rich media [14] where lipid peroxidation was induced by FeSO$_4$ and Malondialdehyde (MDA), produced by the oxidation of polyunsaturated fatty acids, reacts with two molecules of thiobarbituric acid (TBA) yielding a pinkish red chromogen with an absorbance maximum at 532 nm which was measured using a 96 well ELISA plate. Percentage inhibition of lipid peroxidation by different concentrations of the extract was calculated.

#### Determination of total antioxidant capacity

The assay is based on the reduction of Mo(VI) to Mo(V) by the extract and subsequent formation of a green phosphate/Mo(V) complex at acid pH [15]. Each well of a 96 well ELISA plate containing extract and reagent solution (0.6 M sulfuric acid, 28 mM sodium phosphate and 4 mM ammonium molybdate) were incubated at 95°C for 90 min. After the mixture had cooled to room temperature, the absorbance of each solution was measured at 695 nm against a blank. The antioxidant capacity was expressed as ascorbic acid equivalent (AAE).

#### Determination of total flavonoid content

Total flavonoid content was determined using aluminium chloride (AlCl$_3$) according to a known method, 15 using Fisetin as a standard. The date palm extract (0.1 ml) were added to 0.3 ml distilled water followed by 5% NaNO$_2$ (0.03 ml). After 5 min at 25°C, AlCl$_3$ (0.03 ml, 10%) was added. After further 5 min, the reaction mixture was treated with 0.2 ml of 1 mM NaOH. Finally, the reaction mixture was diluted to 1 ml with water and the absorbance was measured at 510 nm. The results were expressed as mg Fisetin/g date palm extract.

#### Determination of total phenolic content

The total phenolic content of the date palm extract was determined using the Folin-Ciocalteau reagent. The reaction mixture contained: 200 μl of diluted extract, 800 μl of freshly prepared diluted Folin Ciocalteu reagent and 2 ml of 7.5% sodium carbonate. The final mixture was diluted to 7 ml with deionized water. Mixtures were kept in dark at ambient conditions for 2 h to complete the reaction. The absorbance at 765 nm was measured. Gallic acid was used as standard and the results were expressed as mg gallic acid (GAE)/g of the date palm extract.

### Results and Discussion

As many as 70% of all drugs used today for the treatment of degenerative diseases due to inflammatory cascades were derived from or based on natural products. Although fruits and vegetables have been linked with reduction of risk of cancer, cardiovascular diseases, autoimmune diseases, and various other chronic illnesses, neither the active components nor their mechanisms of action are well established. Identification of active ingredients in dietary plants, and the cell signalling pathways they modulate, can validate their use in various diseases.

For a long time it has been known that ROS perform essential roles in immune response to pathogens, including bacterial killing through production of superoxide by reduced nicotinamide adenine dinucleotide phosphate (NADPH) oxidases during respiratory burst in activated macrophages and neutrophils [16,17]. This is further corroborated by studies on patients with chronic granulomatous...
The present study date palm extracts were prepared using three different methods and then their anti-inflammatory activities has been evaluated. Also many other plant species have been investigated in the search for novel antioxidants but generally there is still a demand to find more information concerning the antioxidant potential of plant species. It has been mentioned the antioxidant activity of plants might be due to their phenolic compounds. Flavonoids are a group of poly phenolic compounds with known properties which include free radical scavenging, inhibition of hydrolytic and oxidative enzymes and anti-inflammatory activity. Here we have clearly demonstrated that date palm extracts, collected by three different methods hold a potent antioxidant properties by showing DPPH radical scavenging activities (Table 1), hydroxyl radical scavenging (Table 2), superoxide radical scavenging (Table 3), significant inhibition of lipid peroxidation (Table 4). The calculated IC50 values of these three different extracts of

Table 3: Superoxide radical O2•− scavenging activity (Superoxide radical scavenging assay shows that, in this system, the superoxide radical-scavenging activities of the three date palm extracts are in this order: basic ethanolic extract > acidic ethanolic extract > methanolic extract)

Various concentrations of date palm extracts, collected by three distinct methods, scavenge Superoxide radical in a dose-dependent manner \[r²=0.809 \text{ (p<0.01)}\] for methanolic extract; \[r²=0.908 \text{ (p<0.01)}\] for acidic ethanolic extract; \[r²=0.928 \text{ (p<0.01)}\] for basic ethanolic extract As per IC50 values acidic ethanolic extract is more potent to scavenge superoxide radicals (IC50 19.00 µg/ml) than the basic ethanolic extracts (IC50 19.15 µg/ml) and methanolic extracts (IC50 28.88 µg/ml).
date palm advocated the strong antioxidant properties of these crude extracts (Table 5).

**DPPH radical-scavenging activity**

Reactive oxygen species (ROS) cause oxidative modifications to DNA, proteins, lipids, and small intracellular molecules. Lipids, including pulmonary surfactants, react with ROS to produce lipid peroxides, which cause increased membrane permeability and inactivation of surfactants [23]. In turn, reaction of ROS with cellular proteins leads to decreased protein synthesis due to the modification of proteins involved in translation and translocation, ultimately resulting in impaired cellular metabolism. The oxidative stress induced by the overproduction of ROS has been associated with many clinical conditions including cancer, asthma, cystic fibrosis, ischemia-reperfusion injury, drug-induced toxicity and aging.

Antioxidants, on interaction with DPPH transfer an electron (hydrogen atom) to DPPH, neutralizing its free radical character [24]. The colour changes from purple to yellow and its absorbance at wavelength 517 decreases. Various concentrations of date palm extracts, collected by three distinct methods, quenched DPPH free radical in a dose-dependent manner [r2=0.909 (p<0.05) for methanolic extract; r2 = 0.933 (p<0.05) for acidic ethanolic extract; r2=0.930 (p<0.05) for basic ethanolic extract]. IC50 values were 22.91 μg/ml for methanolic extract, 14.61 μg/ml for acidic ethanolic extract and 36.44 μg/ml for basic ethanolic extract. DPPH assay shows that, in this system, the radical-scavenging activities of the three varieties of date palm extracts are in the order acidic ethanolic extract>methanolic extract>basic ethanolic extract.

**Assay of hydroxyl radical (OH)-scavenging activity**

By the addition of iron (II) salts to a phosphate buffer containing reaction mixture, Hydroxyl radicals can be generated [25]. Benzoate, weakly fluorescent, after monohydroxylation forms highly fluorescent hydroxybenzoates [26]. Measurement of this spectrofluorometric changes has been used to detect damage by hydroxyl radical. Date palm extracts collected by three distinctly separate methods was found to be a powerful scavenger of hydroxyl radicals. There is a linear correlation between concentration of extract and OH-scavenging activity [r2=0.832 (p<0.05) for methanolic extracts of date palm; r2 =0.852(p<0.05) for acidic ethanolic extracts of date palm; r2=0.882 (p<0.05) for basic ethanolic extracts of date palm]. IC50 values are 18.20 μg/ml for methanolic date palm extracts, 17.30 μg/ml for acidic ethanolic date palm extracts and 17.00 μg/ml for basic ethanolic extracts. Highest hydroxyl radical-scavenging activity was found in the date palm extract collected by using basic ethanolic methods. The hydroxyl radical scavenging properties of date palm extracts are: basic ethanolic extracts> acidic ethanolic extracts> methanolic extracts.

**Assay of superoxide radical O2- scavengeing activity**

Photochemical reduction of flavins generates O2, which reduces NBT, resulting in the formation of blue formazan [12]. Three types of date palm extracts inhibited the formation of the blue formazan and % inhibition is proportional to the concentration [r2=0.870 (p<0.05) for methanolic extract; r2=0.908 (p<0.05) for acidic ethanolic extract; r2=0.928 (p<0.05) for basic ethanolic extract]. IC50 values were 28.88 μg/ml for methanolic extract, 19.00 μg/ml for acidic ethanolic extract and 19.15 for acidic ethanolic extract. The superoxide ion scavenging activities of all these three extracts are: acidic ethanolic extract> basic ethanolic extract> methanolic extracts.

**Lipid peroxidation assay**

Egg yolk lipids undergo rapid non-enzymatic peroxidation when incubated in the presence of ferrous sulphate. Lipid peroxides are likely involved in numerous pathological events, including inflammation, metabolic disorders and cellular aging [27,28]. Date palm extracts inhibited lipid peroxidation in a concentration-dependent manner [r2 =0.870(p< 0.05) for methanolic extract; r2=0.635 (p< 0.05) for acidic extract].

**Total antioxidant capacity:**

The phosphomolybdenum method is quantitative method to detect the antioxidant activity, expressed as the number of equivalents of ascorbic acid where acidic ethanolic date palm extract had a higher capacity than the basic ethanolic date palm extracts, followed by methanolic date palm extracts.

**Table 4:** Lipid peroxidation inhibition assay (Lipid peroxidation assay shows that, in this system, to prevent the lipid peroxidation, the three date palm extracts are in this order: basic ethanolic extract>acidic ethanolic extract> methanolic extracts)

**Table 5:** Total antioxidant capacity (equivalent to ASA/mg of plant material)

(The phosphomolybdenum method is quantitative method to detect the antioxidant activity, expressed as the number of equivalents of ascorbic acid where acidic ethanolic date palm extract had a higher capacity than the basic ethanolic date palm extracts, followed by methanolic date palm extracts.)
In this study, we clearly demonstrated that date palm extracts, collected by three different methods hold potent anti-oxidative properties by showing DPPH radical scavenging activities (Table 1), hydroxyl radical scavenging (Table 2), superoxide radical scavenging (Table 3), significant inhibition of lipid peroxidation (Table 4). The calculated IC$_{50}$ values of these three different extracts of date palm advocated the strong anti-oxidative properties (Table 5) of these crude extracts and for this reason, we are therefore interested to evaluate the in vivo anti-inflammatory activities of these compounds in preclinical models, but before this cytotoxic and anti-inflammatory properties of these three extracts must be evaluated thoroughly.

Since components of the fruit are also known Aeroallergens and food allergens, we are also currently exploring the allergenic aspects of the same in our on-going in vitro and in vivo studies in tandem with extending the abovementioned findings into their anti-inflammatory potencies [31-35].

Acknowledgement
The work embodied in the study was possible due to a grant from West Bengal department of Biotechnology to ERB (sanction no. WB DBT Sanction No. 608/ BT(Esttl.)R&D-26/09 dt 29-11-2011). The grant also provided fellowship to KM. The authors acknowledge Prof. B. De for providing the extracts.
