ABSTRACT

Background: The emergence of drug resistance in pathogens as well as appearance of undesirable side effects of certain antibiotics has led to the discovery of new antibacterial agents particularly from medicinal plants.

Objective: In this study, we have found the in vitro antibacterial, antifungal and phytotoxicity activity of dichloromethane and methanol extract of leaves of kalanchoe pinnata (lam) pers.

Method: The antibacterial activity of the plant leaves evaluated against microbial flora Bacillus subtilis (PTCC 1207), Bacillus cereus (PTCC 1247), Staphylococcus epidermidis (PTCC 1114) and Escherichia coli (PTCC 1047) antifungal activity against Epidermophyton floccosum, Trichophytum mentogrophytes, T. rubrum, T. simii, T. scheonleinii, Microsporum canis, Pseudallescheria boydii, Candida albicans by using disc diffusion method etc.

Results: Result showed that the tested extracts possess mild or non-significant antimicrobial and antifungal activities. Amoxicillin 10mg/ml was used as standard compound. The leaves extract of dichloromethane and methanol showed less zone inhibition compared than standard compound.

Conclusion: It could be suggested that the dichloromethane and methanol extracts of Kalanchoe pinnata leaves possess non-significant antibacterial and anti-fungal activities.

Keywords: Kalanchoe pinnata, disc diffusion, Phytotoxicity

INTRODUCTION

Kalanchoe pinnata (Lam., syn. Bryophyllum pinnatum, B. calycinum; Local name: Pathorkuchi, Coughpatha; English name: Air plant; Family: Crassulaceae) is an herb found ubiquitously in nature. It has tall hollow stems, fleshy dark green leaves that are distinctly scalloped and trimmed in red, and bell-like pendulous flowers1. Kalanchoe pinnata (K. pinnata) has become naturalized in temperate regions of Asia, Australia, New Zealand, West Indies, Macaronesia, Mascarenes, Galapagos, Melanesia, Polynesia, and Hawaii. It is also widely distributed in the Philippines, where it is known as katakataka or katakataka which means astonishing or remarkable1, 2. The leaves of K. pinnata have a variety of uses in the traditional system of medicine in Pakistan. They are eaten for diabetes, diuresis, dissolving kidney stones, respiratory tract infections, as well as applied to wounds, boils, and insect bites1. The main plant chemicals found in kalanchoe alkaloids, triterpenes, glycosides, flavonoids, cardenolides, steroids, bufadienolides and lipids3-5 include: arachidic acid, astragalin, behenic acid, beta amyrin, benzenoids, beta-sitosterol, bryophollenone, bryophollone, bryophyllin, bryophyllin A-C, bryophyllum, bryophylnol, bryotoxin C, bufadienolides, caffeic acid, campesterol, cardenolides, cinnamic acid, clerosterol, clionasterol, codisterol, coumaric acid,
epigallocatechin, ferulic acid, flavonoids,friedelin, glutinol, hentriacontane, isofucosterol, kaempferol, oxalic acid, oxalacetate, palmitic acid, patuletin, peposterol, phosphoenolpyruvate, protocatechuic acid, pseudotaraxasterol, pyruvate, quercetin, steroids, stigmasterol, succinic acid, syringic acid, taraxerol, and triacontane.

The leaves and bark are bitter tonic, astringent to bowels, analgesics, carminative and useful in diarrhoea and vomiting. Antiulcer activities of the leaf were also reported. Several other biological activities have been reported for *Kalanchoe pinnata* Linn. The plant has hepatoprotective activity and is also used to increase vascular integrity, to treat hypertension and to enhance the dropping of umbilical cord of a newly born baby. The leaves of the plant are eaten to control diabetes. They are diuretic, and applied to wounds, boils and bites of insects. Leaf juice is used in the treatment of coughs, bronchial affections, blood dysentery, jaundice and gout. *Bryophyllin* compounds have marked anticancer therapeutic values against cancer cells. Immumomodulatory effect. Alcoholic extracts of the leaves showed potent antioxidant activity. Studies on medicinal plant are necessary because there are still plants like *Kalanchoe pinnata* whose medicinal uses have not been fully ascertained in all dimensions. With the emergence of resistant strains of microbes to most existing antibiotics, there is need to challenge them by making continuous frantic search for new more active antimicrobial agents against them. Therefore, present study was designed to scientifically assess the antimicrobial activities of extracts of *Kalanchoe pinnata* on *E.coli*, *Staphylococcus aureus*, *Pseudomonas aeruginosa* and *Candida albicans* and carry out phytotoxicity activity of the extract.

**MATERIAL AND METHODS:**

**Phytotoxicity activity**

Lemna minor was used as a test organism. The experimental conditions included light intensity (9000 Lux), photoperiod (12 hours), incubation condition (28º C, 56 + 1% rh). Phytotoxic activity of the extracts was carried out against the *L. minor* following McLaughlin et al. (1991) and Nisar et al. (2011). Ten grams of leaves of plant was soaked in 90 ml of distilled water and twenty grams of the same plant were soaked in 80 ml of distilled water as two standard solutions of distilled water in conical flasks. The flasks were covered with aluminum foil and allowed to stand at 25 º C for 48 hrs. The extracts were filtered by Whatman filter paper. The dichloromethane and methanol extracts were further diluted by diluting the initial concentration by a factor of Ghulam Dastagir and Farrukh Hussain. Phytotoxic and insecticidal activity of plants... 84 twenty e.g., (10 ml + 90 ml, 30 ml+70 ml, 50 ml+50 ml, 90 ml +10 ml) plants extracts + distilled water, respectively. The various dilutions were tested for phytotoxicity against *L. minor*. E-medium was prepared by mixing various constituents in 1000 ml distilled water and pH was adjusted between 5.5-6.0 by adding KOH pellets. The constituents and their respective proportions are: 1. Potassium dihydrogen phosphate (0.68gm/L). 2. Potassium nitrate (1.515gm/L). 3. Calcium nitrate (1.180gm/L). 4. Magnesium sulphate (0.492gm/L). 5. Boric acid (0.00286gm/L). 6. Magenous chloride (0.00362gm/L). 7. Ferric chloride (0.00540gm/L). 8. Zinc sulphate (0.00022gm/L). 9. Copper sulphate (0.00022gm/L). 10. Sodium molybdate. 11. Ethylene diamino tetracetic acid. The E-medium was autoclaved at 121 ºC for 15 min. Fifteen (15 mg) of extract was dissolved in 1.5 ml of solvent (Methanol/n-hexane) serving as stock solution. Three sterilized flasks were incubated with 10 μl, 100 μl and 1000 μl of solution pipetted from the stock solution and added to the flasks containing Lemna plants. Twenty ml of E-medium was added to each flask. Other flasks were supplemented with Emedium only as control. Plants were examined daily during incubation. Flasks were placed in growth cabinet for 7 days. The number of fronds / flask were counted and recorded on seventh
day. Results were analysed as growth regulation in terms of percentage as described by \(^{15}\) (Nisar et al., 2011).

**Antimicrobial assay**

The antibacterial activity of the methanol extract were determined against *Bacillus subtilis* (PTCC 1207), *Bacillus cereus* (PTCC 1247), *Staphylococcus epidermidis* (PTCC 1114) and *Escherichia coli* (PTCC 1047) using the disc diffusion method. Muller- Hinton agar (MHA) (Oxoid) was used as bacterial medium. The filter paper discs (6 mm in diameter) were individually impregnated with 10 μL of the stock solution of the extract (4 mg mL\(^{-1}\)) and then placed onto the agar plates which had previously been inoculated with the tested microorganisms. The plates were inoculated with bacteria incubated at 37°C for 24 h. The diameters of inhibition zones were measured in millimeters. All the tests were performed in duplicate. Gentamicin (30 μg) served as the positive control \(^{16}\).

**Antifungal Assay**

In vitro antifungal screening was performed by disc diffusion assay method \(^{17, 18}\) where Potato Dextrose Agar (PDA) medium was used for the antifungal activity. Their antifungal activity were tested against six fungal strains at a concentrations of 250 μg/disc, 500 μg/disc for each and the results were compared with griseofulvin (500 μg/disc). The activity was determined after 72 hours of incubation at 37.5°C.

**RESULTS:**

**Anti-bacterial assay:**

It has been concluded that tested plant extracts possess no significant anti-bacterial activity against selected strain as in tab.1

Phytotoxicity assay:
Sample of KPLM showed moderate activity while sample of KPLD showed no activity against the tested plant.

DISCUSSION:
Plants are employed as important source of medication in many traditional medications. In the present study, the antibacterial test was performed using the disc diffusion method. The antibacterial activities of extracts were assessed against mentioned bacterial strains. In this experiment, both extracts showed non-significant sensitivity to the different strains of bacteria. The antifungal activity was determined results were showing in table 2.

CONCLUSION:
Finally, it could be suggested that the dichloromethane and methanol extracts of Kalanchoe pinnata leaves possess non-significant antibacterial and anti-fungal activities. The experiment was only conducted with certain species of bacteria and fungus as test samples. Therefore, further research is essential to evaluate the sensitivity of plant extract against other species of bacteria, fungi, virus etc. Further studies are however recommended on the plant to determine the pharmaceutical potentialities of the plant as a medicine and to isolate and elucidate the structure of the bioactive compounds.
