Abstract

Segmental resection is the one of the reason of deviation of mandible. Patients undergoing hemimandibulectomy due to benign and malignant tumours leads to rotation of mandible. This case report describes prosthodontic rehabilitation of hemimandibulectomy subject with additional row of teeth in the maxillary complete denture.

Keywords: Hemimandibulectomy; Two rows of teeth; Prosthetic rehabilitation

Introduction

Odontogenic tumours of epithelial origin commonly seen in the posterior mandible are often treated with surgical resection [1]. Patients undergoing hemimandibulectomy poses most challenging maxillofacial endeavours to prosthodontist. Disorientation of the mandible leads to psychological, aesthetic and masticatory deformities. Cantor and Curtis classified hemimandibulectomy as follows [2]

Class 1: Mandibular resection involving alveolar defect along with preservation of mandibular continuity.

Class 2: Resection defects involve loss of mandibular continuity distal to cuspid.

Class 3: Defect involve loss upto the mandibular midline region.

Class 4: Defect involves loss upto midline region.

Class 5: Anterior bone graft surgical reconstruction.

Class 6: Resection of the anterior portion without reconstruction.

Unhelpful limiting factors like improper orientation of resected mandible, leading to deviation of the mandible to the resected side and limiting coordination, facial asymmetry, muscular imbalance. It also leads to other problems such as phonetics, mastication and mandibular movements [3].

Different treatment options are available for the prosthetic rehabilitations such as use of palatal ramp and guiding flange [4]. Rosenthal advocated use of anatomic teeth double rows on the undefective side. Different treatment approaches uses two rows of anatomic teeth: one in an occlusal position and the other supporting condyle on left side (Figure 1). Due to economic constraint grafts resection of the mandible distal to lateral incisor on the left side up were extracted. There was deviation of the mandible on the resected side (Figure 2). A PA mandible X-ray revealed resection of the mandible distal to lateral incisor on the left side up to condyle on left side (Figure 3). Due to economic constraint grafts and implant placement on the defect side was not possible therefore prosthetic rehabilitation of hemimandibulectomy with twin occlusion was planned.

Before any prosthetic treatment could begin, the patient was asked

to follow an exercise regime. It comprised of placing the right thumb inside the corner of the mouth on the left side and to stretch the cheek laterally for three sets of five stretches at least twice a day.

**Procedure**

The primary impressions were made with alginate for the maxillary arch and mandibular arch on stock plastic tray (Figure 4). Special tray was constructed on maxillary arch. Custom trays were fabricated with care taken to block the present teeth in mandibular arch. Border moulding was done and final impression were made with zincoxide eugenol paste in maxillary arch. In the mandibular arch after border moulding and final impression of mandibular arch with ZOE paste. Medium body was utilised to record resected tissue and then a plastic tray was used to record present teeth and definitive casts were obtained (Figure 5). Vertical dimension was assessed by closest speaking space method. Centric relation record was recorded. Twin occlusion using anatomic teeth were arranged on the healthy mandibular side. Teeth were occlusally grinded for removing interfences in lateral direction (Figure 6). Try in was checked for esthetics, phonetics, lack of cuspal interference and occlusion. The dentures were processed and checked intraorally (Figures 7 and 8). Any interfences were corrected and patient was given instructions. Patient was heavily motivated and ask to make repetitive efforts so as to adapt to new dentures. Different exercises were suggested to the patient so that he can adapt the mandibular denture into centric occlusion. Patient was recalled after one week and patient expressed satisfaction in esthetics, phonetics and masticatory efficiency (Figures 9 and 10).

**Discussion**

There were several physical limitations seen in hemimandibulectomy edentulous patients like surgical skin grafts, deviated mandible, and unfavourable ridges. The present article explains successful management of hemimandibulectomy patient. Twin occlusal technique not only improves masticatory ability but also supports cheeks thereby improving aesthetics and phonetics [5-7]. This eliminates lateral stress that would destabilize mandibular denture. Implants also serve as another option in resected mandible but it is costly and technique sensitive [9]. The Guide Flange Prosthesis can be regarded as a training type of prosthesis. If the patient can successfully repeat the mediolateral position, the GFP can often be discontinued [10-13]. Another technique by Rathee et al., described a simple method for fabrication of customized wire-made-guide flange removable prosthesis to aid in the reducing the mandibular deviation and enhances the masticatory efficiency. Low weight prosthesis with low-cost is conservative rehabilitation prosthesis for hemimandibulectomy patients [8,11].

**Conclusion**

Patient motivation and education was the basic principle for successful rehabilitation of any prosthetic treatment. In this article author incorporates two rows of anatomic posterior teeth in maxillary denture to impart stability and broader occlusal table. Though surgical reconstructions by grafts and implants were not possible in every patient because of economic constraints, alternative prosthetics rehabilitation has to be considered to restore aesthetics and mastication in hemimandibulectomy subjects.
