Abstract

Due to the special affinity on tumor cells and anti-cancer activity for 5-iodo-4-thio-2’-deoxyuridine, the interactions between 5-iodo-4-thio-2’-deoxyuridine and human serum albumin (HSA) were investigated with the fluorescence spectroscopy. The results showed that 5-iodo-4-thio-2’-deoxyuridine on human serum albumin (HSA) had a dynamic fluorescence quenching. The main forces of both interactions have typical hydrophobic interaction from thermodynamic data to determination. The conformation of 5-iodo-4-thio-2’-deoxyuridine on human serum albumin was studied using synchronous fluorescence spectroscopy. The experimental result was in correspondence with molecular modeling theory. This work would be useful to understand the state of the transportation, distribution, and metabolism of the anticancer drug in human body, these results may be of significance in pharmacology and clinical medicines.

Keywords: 5-iodo-4-thio-2’-deoxyuridine; Human serum albumin (HSA); Nucleoside; Fluorescence spectroscopy, Molecular modeling

Introduction

The application of modified nucleosides

Human serum albumin (HSA) is an important and the most abundant protein constituent of blood plasma and serves as a protein storage component. Recently, crystallographic studies of HSA have revealed that the protein, a 585 amino acid residue monomer, contains three homologous α-helical domains (I-III), and a single tryptophan (Trp214) [1]. HSA considerably contributes to colloid osmotic blood pressure and realizes the transportation and distribution of many molecules and metabolites such as fatty acids, amino acids, hormones, cations and anions, and many diverse drugs. It also makes possible to bind and carry many drugs through the bloodstream, which are poorly soluble in water [2]. Therefore, it is important to study the interaction of drug with the protein because protein-drug binding plays an important role in pharmacology and pharmaco dynamics. We can obtain a lot of information on the interaction between serum albumin and drug, which can help us better understand the absorption and distribution of the drug.

Nucleosides and their derivatives exhibit significant anti-tumor, antiviral and antibacterial activities [3]. It is recognized that nucleosides have the most potential function to restrain virus [4]. Extensive investigations into the interaction between the serum albumin and internal compound or pharmaceutical molecule have been made, but the interaction of protein with the nucleoside drug has seldom been reported [5]. In a series study methods concerning the interaction between drugs and protein, fluorescence techniques are great aids in the study of interactions between drugs and plasma proteins in general and serum albumin in particular because of their high sensitivity, rapidity, and ease of implementation [6], because such studies can provide information on the features affect the therapeutic effect of drugs. 5-iodo-4-thio-2’-deoxyuridine is one of important modified nucleosides, which oxygen atom was replaced by sulfur atom at 4-position in pyrimidine ring. In 2015, Zhang and Xu noticed that 5-iodo-4-thio-2’-deoxyuridine (4-SIdU) exhibited great anti-tumor activity for oral tumor which could kill cancer cells with UV A, so it can be a potential, nucleosides anti-tumor drug [7,8]. Therefore, it is of important worthiness and significance to investigate the interaction between 5-iodo-4-thio-2’-deoxyuridine and human serum albumin.

In this paper, we studied the interaction of 5-iodo-4-thio-2’-deoxyuridine with HSA at three temperatures under simulation of physiological conditions utilizing fluorescence in combination with molecular modeling. In the meantime, the binding mechanism of 5-iodo-4-thio-2’-deoxyuridine to HSA was discussed, and the binding parameters of the reaction were calculated according to fluorescence data.

The structure of 5-Iodo-4-thio-2’-deoxyuridine

The structure of 4-SIdU was showed in Figure 1. It is similar to the structure of 5-iodo-2’-deoxyuridine, with a thio atom instead of an oxygen atom at the C-4 position of the 2’-deoxyuridine. The pyrimidine base is of importance to bind to nucleic acid. The pyrimidine base can be attached to the shunt glucose molecule and HSA binds to serum albumin, which is a property of the drug. This indicates that 5-iodo-4-thio-2’-deoxyuridine (4-SIdU) is a potential anti-cancer drug and can be used as a new treatment for oral cancer.

containing thio carbonyl is redshift in maximum absorption peaks of UV and extremely sensitive to light. Therefore, a low dose near ultraviolet light can stimulate sulfur atom in thiocarbonyl for the electron transition which is destroying the structure of the compound 4-SIdU (Figure 1).

Experimental Section

Materials and apparatus

UV-VIS spectrophotometer (JASCO, Japan); FP-6500 spectrofluorimeter (JASCO, Japan); pH-4 digital pH-meter (Shanghai Lei Ci Device Works, Shanghai, China); JULABO-F12 thermostat (Germany, ± 0.01°C); FA1004 Electronic balance (Shanghai Jing Ke Device Works, Shanghai, China)

Interaction with human serum albumin (HSA)

HSA (Sigma) was directly dissolved in double distilled water to prepare the stock solution (1.0 × 10⁻⁶ mol L⁻¹ HSA), and the stock solution was kept in the dark at 0-4°C; 1.0 × 10⁻³ mol L⁻¹ 5-iodo-4-thio-2'-deoxyuridine solution was obtained by dissolving it in double distilled water. 0.1 mol L⁻¹ Tris-HCl buffer solution of pH 7.4, 0.1 mol L⁻¹ NaCl working solution. Unless otherwise mentioned, all chemicals were of analytical reagent grade and were used without further purification. Double distilled water was used throughout the experiment.

UV absorption spectroscopy experiments of 5-iodo-4-thio-2'-deoxyuridine: Pipette 2ml concentrated solution of 1 × 10⁴ mol/L of human serum albumin solution to a 1cm quartz cuvette, Tris-HCl buffer solution as a reference, followed by adding an appropriate amount of micro-injector 5-iodo-4-thio-2'-deoxyuridine solution, allowed to stand for 3min, the UV absorption spectrum was measured at 220 – 450 nm (5-iodo-4-thio-2'-deoxyuridine solution was added a total volume of less than 50 μL).

Fluorescence spectroscopy experiments of 5-iodo-4-thio-2'-deoxyuridine: The quantitative analysis of the potential interaction between 5-iodo-4-thio-2'-deoxyuridine and HSA were performed by fluorescence titration (cumulative total volume of less than 50 μL). The reaction was carried out by mixing 2.5ml concentration of 1 × 10⁻⁶ mol/L of HSA stock solution with appropriate amount of 1.0 × 10⁻³ mol L⁻¹ 5-iodo-4-thio-2'-deoxyuridine in the optical path of 10mm quartz cuvette, gently shaken, allowed to standing for 3 min. At 280 nm for the excitation wavelength of excitation and emission slit widths 5 nm/5 nm, the scanning speed was 500 nm/min, 0.05 mol/L Tris-HCl buffer solution as a blank correction. The fluorescence spectra of the concentration of 5-iodo-4-thio-2'-deoxyuridine were recorded by 290-450 nm on a fluorescence spectrophotometer under the action of the fluorescence quenching, 300 k, 310 k, and processing by the same method.

Fluorescence spectroscopy experiments of 5-iodo-4-thio-2'-deoxyuridine: The quantitative analysis of the potential interaction between 5-iodo-4-thio-2'-deoxyuridine and HSA were performed by fluorescence titration (cumulative total volume of less than 50 μL). The reaction was carried out by mixing 2.5ml concentration of 1 × 10⁻⁶ mol/L of HSA stock solution with appropriate amount of 1.0 × 10⁻³ mol L⁻¹ 5-iodo-4-thio-2'-deoxyuridine in the optical path of 10mm quartz cuvette, gently shaken, allowed to standing for 3 min. At 280 nm for the excitation wavelength of excitation and emission slit widths 5 nm/5 nm, the scanning speed was 500 nm/min, 0.05 mol/L Tris-HCl buffer solution as a blank correction. The fluorescence spectra of the concentration of 5-iodo-4-thio-2'-deoxyuridine were recorded by 290-450 nm on a fluorescence spectrophotometer under the action of the fluorescence quenching, 300 k, 310 k, and processing by the same method.

Synchronous fluorescence spectra: Synchronous Fluorescence Spectra were scanned on the same condition in section 4.2.2. The spectra were measured at two different $\Delta \lambda$ (Δλ = $\lambda_{em} - \lambda_{ex}$) values, 15 nm and 60 nm.

Circular dichroism: Circular dichroism (CD) measurements were performed on a J-810 Spectropolarimeter (Jasco, Tokyo, Japan) at room temperature. CD measurements of HSA in the absence and presence of caffeine were recorded in the range of 260-200 nm. The instrument was controlled by Jasco's Spectra Manager TM software. Quartz cells having path lengths of 0.1 cm were used at a scanning speed of 1000 nm/min. The data were expressed in terms of molar ellipticity, [θ]. An appropriate buffer solution run under the same conditions was taken as a blank and subtracted from the sample spectra.

Molecular modeling study

The initial structures of all the molecules were generated by molecular modeling software Sybyl 6.9.1. The potential of the 3D structures of HSA was assigned according to the Autodock 4.0 force field with Kollman-all-atom charges. The geometries of the antitumor drug (5-iodo-4-thio-2'-deoxyuridine) subsequently optimized using the Tripos force field with Gasteiger-Masili charges. The AutoDock 4.0 program was used to calculate the interaction modes between the drug and HSA. The Lamarckian Genetic Algorithm (LGA) applied in AutoDock was applied to calculate the possible conformation of the drug that binds to the HAS. During the docking process, a maximum of 10 conformers was considered for the drug. The conformer with the lowest binding-free energy was used for further analysis. All calculations were performed on SGI FUEL workstations.

Results and Discussion

Interaction with human serum albumin (HSA)

UV-vis absorption spectra: In order to confirm the probable quenching mechanism, the UV-vis absorption spectra of 5-iodo-4-thio-2'-deoxyuridine and HSA and the difference absorption spectrum [[HSA-5-iodo-4-thio-2'-deoxyuridine]-[5-iodo-4-thio-2'-deoxyuridine]] were also investigated (Figure 2). It can be seen from Figure 2 that the ultraviolet absorption peak between the 5-iodo-4-thio-2'-deoxyuridine and HSA was significantly different, while the ultraviolet absorption peak of HSA is almost no change by adding 5-iodo-4-thio-2'-deoxyuridine after from the experimental results, which confirms that the interaction between 5-iodo-4-thio-2'-deoxyuridine and HSA is mainly a dynamic quenching process [9].

Fluorescence spectra and quenching mechanism

Fluorescence quenching spectra study: The light from intrinsic fluorescence of the protein comes mainly from tryptophan, tyrosine and phenylalanine residues [10]. Due to quantum yield of phenylalanine is very low, where tyrosine is ionized or close to the amino and carboxyl group or tryptophan, and their fluorescence almost all quenched. The active sites in protein, HSA has only one tryptophan residue Trp214, the maximum emission wavelength at 332 nm, the intrinsic fluorescence of HSA is almost contributed by tryptophan residue, actually, tryptophan alone [11].

Figure 2: The UV-vis absorption spectra of HSA in the absence and presence of 5-iodo-4-thio-2'-deoxyuridine. Curve B, the absorption spectrum of 5-iodo-4-thio-2'-deoxyuridine only; curve D-M, the difference absorption spectrum between 5-iodo-4-thio-2'-deoxyuridine-HSA and 5-iodo-4-thio-2'-deoxyuridine, n (HSA): n (5-iodo-4-thio-2'-deoxyuridine)=1: 2, 4, 6, 8, 10, 12, 14, 16, 18, 20.
The fluorescence emission spectra of HSA at 5-iodo-4-thio-2'-deoxyuridine various concentrations and an excitation wavelength of 282 nm in Tris-HCl buffer solution (pH=7.4) at 27°C. Curve a, C (HSA) =6 μmol/L of the 5-iodo-4-thio-2'-deoxyuridine, curve b-h, the difference absorption spectrum between 5-iodo-4-thio-2'-deoxyuridine-HSA and 5-iodo-4-thio-2'-deoxyuridine, n (HSA) : n (4-SIdU) =1: 2, 4, 6, 8, 10, 12.

The fluorescence spectra of HSA at various concentration of 5-iodo-4-thio-2'-deoxyuridine are shown in Figure 3. Obviously, HSA has a strong fluorescence emission band at 332 nm while 5-iodo-4-thio-2'-deoxyuridine has no intrinsic fluorescence under the present experiment conditions when fixing the excitation wavelength at 282 nm. The fluorescence emission intensity of HAS decreases regularly with the increase of 5-iodo-4-thio-2'-deoxyuridine concentration. The strong quenching of HSA fluorescence clearly indicates that it has interacted with 5-iodo-4-thio-2'-deoxyuridine. The microenvironment around the Trp214 residue and the tertiary structure of HSA were interacted with 5-iodo-4-thio-2'-deoxyuridine. The microenvironment and the presence of quencher at concentration [Q]; and Kq0 is the effective quenching constant for the accessible fluorophores.

Quenching mechanism and binding constants: Fluorescence quenching refers to any process that decreases the fluorescence intensity of a sample. A variety of molecular interactions can result in quenching. It is important to recognize that the phenomenon of collisional quenching results in the expansion of the volume and distance within the solution which affects the fluorophore. The root-mean-square distance that a √∆x2. Fluorescence quenching process may be between molecules combined into a complex dynamic quenching.

By Lineweaver-Burk double reciprocal plotting (F 0-F)-1 on [Q] -1, it can be seen from Figure 5, curve linear relationship is good, the slope of the curve decreased as the temperature increased, respectively, by the reciprocal of the slope of the line can be determined at different temperatures of 5-iodo-4-thio-2'-deoxyuridine with human serum albumin in the dissociation constants and the correlation coefficient (see Table 2), as the temperature increases, the dissociation constant increases, the bonding between them is weakened. Thus, 5-iodo-4-thio-2'-deoxyuridine can be stored and removed by protein in the human body.

ΔG = ΔH − TΔS

(5)

Where R is the gas constant, K is the binding constants at temperature. By plotting the binding constants ln to 1/T (Figure 7).

Enthalpy change (ΔH) and entropy (ΔS) can be calculated by a straight line slope and intercept values, and thus according to the equation (6), free energy change (ΔG) can be calculated for the reaction.

ΔG = ΔH − TΔS = −RT ln K

(6)

According to the above formula and the binding constants under different temperature, the thermodynamic parameters of the 4-SIdU and HSA system were calculated. As can be seen from Table 4, free energy change (ΔG) of 5-iodo-4-thio-2'-deoxyuridine is negative, which indicates that 5-iodo-4-thio-2'-deoxyuridine and HSA is a spontaneous process. The negative enthalpy (ΔH) and entropy (ΔS) values of the interaction of 5-iodo-4-thio-2'-deoxyuridine and HSA, that is ΔH<0, ΔS<0, indicate that the binding is mainly enthalpy(ΔH)-
driven and the entropy (ΔS) is unfavorable. This shows that the main role is hydrogen bonds and Van’t der Waals forces between 5-iodo-4-thio-2'-deoxy-uridine and HSA [16]. Hydrogen bonds are specific and directed and are probably best identified through negative of its enthalpy change (ΔH) value, we can exactly pointed out that the presence of hydrogen bonding between them.

Energy transfer between 5-iodo-4-thio-2'-deoxyuridine and HSA: Fluorescence resonance energy transfer (FRET) is a spectroscopic method that can monitor the proximity and relative angular orientation of fluorophores. The donor and acceptor fluorophores can be entirely separated or attached to the same macromolecule. The energy transfer can be replaced through direct electrostatic interaction between the initially excited molecule and its neighbors [17,18].

Förster dipole-dipole non-radiative energy transfer theory [19] that (1) the energy between the donor and acceptor molecules non-radiative energy transfer must meet: donor fluorescence emission spectrum and acceptor absorption spectra between appropriate overlap and the maximum spacing of no more than two molecules 7 nm; (2) the role of donor-acceptor distance can be accurately calculated by the following maximum spacing of no more than two molecules 7 nm; (2) the role of donor-acceptor distance can be accurately calculated by the following maximum spacing of no more than two molecules 7 nm: 1.336, φ = 0.118 [21]. The value of the overlap integral calculated from Figure 8 is \( J = 3.66 \times 10^{-4} \text{ cm}^{-1} \text{ mol}^{-1} \), and thus according to eqs. (8)-(10), we can calculate values of \( R_0 = 2.76 \text{ nm} \) and \( r = 3.32 \text{ nm} \). When a fluorophore gives the average distance between the body and the fluorophore acceptor in the 2-8 nm range and meet 0.5 \( R_0 < r < 1.5 R_0 \), [22], can be highly probable energy transfer between them. That was, the distance between 5-iodo-4-thio-2'-deoxyuridine and tryptophan residue in HSA was 3.32 nm which value was smaller than 7 nm, confirming quenching interaction between 5-iodo-4-thio-2'-deoxyuridine and HSA. All these data that indicate the quenching effect between 5-iodo-4-thio-2'-deoxyuridine and HSA provides a theoretical basis.

Investigation of conformational changes on binding of 5-iodo-4-thio-2'-deoxyuridine to HSA

Synchronous fluorescence spectroscopy studies: Synchronous fluorescence spectroscopy can give information about the molecular environment in the vicinity of the chromosphere molecules at low concentrations under physiological condition. It involves the simultaneous scanning of the excitation and the fluorescence monochromators of a fluorimeter, while maintaining a fixed wavelength difference (Δλ) between them [23]. Therefore, the conformational changes of HSA were evaluated by measuring the synchronous fluorescence intensity of protein amino acid and residues, both before and after the additions of complex. Amino acid residues of the maximum emission peak positions associated with the polarity of the microenvironment of the changes in protein conformation, it can be judged from the maximum emission peak bit changes: the maximum emission wavelength of blue-shift that increased hydrophobicity of the amino acid residues in their environment, red-shift indicates that polarity increased [24]. When the Δλ = λ−λmax between excitation and emission wavelength is fixed at Δλ = 15 nm or Δλ = 60 nm, the synchronous fluorescence gives characteristic information about the tyrosine or tryptophan residues, respectively [25,26]. It can be seen from Figure 9 that when Δλ was set at 15 nm (Figure 9 (left)), the maximum emission wavelength undergoes a more slight red-shift of 0.4 nm (from 300.4 nm to 300 nm) for the investigated concentration range; when Δλ = 60 nm (Figure 9 (right)), the maximum emission wavelength shows a more red-shift of 0.2 nm (from 340.6 nm to 340.8 nm). The change of these data is so very a little that explains hydrophobicity or polarity of the amino acid residues in their environment.

It was found the degree of fluorescence quenching of the Tyr residues was greater than that of Trp residues by Synchronous fluorescence spectroscopy of residues in Tyr and Trp. This suggested that the CD-SldU is more close to Tyr residues of HSA. The reason of 4-SldU quenching of Trp residues of HSA may be due to the CD-SldU molecular motion around Trp214 residue of the HSA protein active sites suitable range, it is possible to quench off the fluorescent of Trp residues by way of dynamic quenching and energy transfer. In addition, it was also found that the maximum emission peak at position basically unchanged by the synchronous fluorescence spectra of the two amino acid residues, this suggests that the maximum emission peak description the 4-SldU their microenvironment had little effect and did not lead to changes in the conformation of the protein molecule.

The CD spectra of interaction between HSA and 5-iodo-4-thio-2'-deoxyuridine: The secondary structure of the protein molecules

\[
E = 1 - \frac{F}{F_0} = \frac{R_0^6}{R_0^6 + r^6}
\]

\[
R_0^6 = 8.79 \times 10^{-25} K^2 n^4 \phi J
\]
caused by some of the reactions was sensitively detected by the circular dichroism spectra. The circular dichroism spectra of interaction between HSA and 5-iodo-4-thio-2'-deoxyuridine are shown in Figure 9. There are two negative bands at 208 nm and 222 nm in the circular dichroism spectra, which is a typical α-helix structure of the CD spectra signal. A reasonable explanation is that the negative peaks between 208 nm and 222 nm both arise from n→π* transfer in the peptide bonds of the α-helix [27]. It can be seen from Figure 10 when the concentration of 5-iodo-4-thio-2'-deoxyuridine is increased to 1.4 × 10^-4 mol/L, in other words, the binding of 5-iodo-4-thio-2'-deoxyuridine from 2.0 × 10^-5 mol/L gradually decreased the intensities of both of these bands, clearly indicating a decrease in the α-helix content of the protein. The secondary structure of the protein molecules HSA to 5-iodo-4-thio-2'-deoxyuridine binds with the amino acid residues of the main polypeptide chain of the protein and destroys their hydrogen bonding networks [28]. The results showed that 5-iodo-4-thio-2'-deoxyuridine role in the process of tumor cells by blood affect the structure of HSA is a small, there are extremely weak changes in the secondary structure of HSA. These indicate that the kinds of anti-tumor drugs in the human body are almost no change in the secondary structure of HSA. Therefore, HSA is a kind of the carrier protein which can safely carry anti-tumor drugs (5-iodo-4-thio-2'-deoxyuridine) to reach the affected area of tumor cells [29].

Molecular modeling study of the interaction between HSA and 5-iodo-4-thio-2'-deoxyuridine

Some researcher have shown that HSA is able to bind many ligands in several binding sites [1,30-32]. From the 3D structure of crystalline albumin, there are three homologous (denoted I, II and III) included in the sites of HSA, such as, I comprises residues (1-195), II (196-383); and III residues (384-585), each with two subdomains, A and B possessing common structural patterns. It is suggested that the principal regions of ligand binding to HAS are located in hydrophobic cavities in subdomains II A and III A, which are accordance with site I and II, respectively, and one tryptophan residues (Trp-214) of HSA is in subdomain II A [2]. There is a large hydrophobic cavity reflect in subdomain II A that many drugs can also bind. The crystal structure of HSA was taken from the Brookhaven Protein Data Bank (entry code 1H9Z) [32]. The potential of the 3D structure of HSA was assigned according to the Amber 4.0 force field with Gasteiger-Marsili charges. The Autodock 4.0 program was used to calculate the interaction between the ligands and HAS [34,35].

The best energy ranked result is shown in Figure 11. In addition, Figure 12 shows the macroscopic viewer of the interaction between drug and HSA. It was evident that 5-iodo-4-thio-2'-deoxyuridine molecule was located in the subdomain II A hydrophobic cavity, and 5-iodo-4-thio-2'-deoxyuridine was adjacent to hydrophobic residues, such as Trp-214, Lys-199, Phe-211, Ser-202, Ala-210, Phe-206, Leu-347, Leu-481 of subdomain II A of HSA. It is suggested that the existence of hydrophobic interaction between them. Further, this finding provides a good structural basis to interpret the efficient fluorescent quenching of HSA emission in the process of 5-iodo-4-thio-2'-deoxyuridine. From the Figure 11, there is a weak hydrogen bond between 5-iodo-4-thio-2'-deoxyuridine and the residues (Phe-206), so, the hydrogen bond is not displayed. The results obtained from modeling confirmed that the interaction between 5-iodo-4-thio-2'-deoxyuridine and HSA was mainly dominated by hydrophobic force.

Conclusion

Based on a special affinity on tumor cells and anti-tumor activity for nucleoside compounds, 5-iodo-4-thio-2'-deoxyuridine was studied. An approach for studying the binding of 5-iodo-4-thio-2'-deoxyuridine to HSA was provided by employing different optical techniques such as fluorescence spectroscopy, UV-vis absorption spectroscopy and CD spectroscopy in this paper. The results of spectral peak intensity decreased in synchronous fluorescence and fluorescence calculation procedure, while the results of ultraviolet and circular dichroism indicate that protein structure was confirmed by the results of molecular modeling. These results could be of significance in pharmacology and clinical medicines. The static fluorescence quenching procedure, while the results of molecular modeling. These results could be demonstrated using tryptophan fluorescence quenching. Int J Biol Macromol 34: 333-337.
