## Abstract

Latex of *F. botryocarpa* fruit is applied on skin infections in Papua New Guinea ethnotherapeutic practices. Systematic bioassay guided separation and isolation of subsequent fractions of latex extracts resulted in three bioactive fractions. Structures were determined by physical ( $M_{pt}$  and  $R_f$  values) and spectroscopic (1D- $^1H$  NMR, 2D-HSQC NMR, 2D-HMBC NMR) and MS ESI-POS. The two methylene protons (2H-1) and 2H-3) resonate as triplets at  $\delta$  3.59 and  $\delta$  4.99 respectively. Electron dense  $\delta$  4.99 (2H-3) on (C-3) depicts the strong electron withdrawing component, quaternary nitrogen (=N=+). Protons resonating at  $\delta$  3.88 and  $\delta$  3.89 are singlets depicting two methoxy groups. Both  $\delta$  3.88 and  $\delta$  3.89 are para-aryls substituents. All isolates, (1), (2) and (3) were identified to be ficuseptine. 2D-NMR and MS of (2) found it to be ficuseptine chloride "2, 3-dihydro-6, 8-bis (4-methoxyphenyl)-1,2,3-trihydroindolizidinium chloride". The counter ions were not established and provide promising lead for further investigation.

**Keywords:** *Ficus botryocarpa*; Latex; Antimicrobial activity; Ficuseptine; Skin infection

## Introduction

Fruit latex of *F. botryocarpa* was used to treat sores, wounds and other superficial skin infections in East Sepik Province, Papua New Guinea (PNG) [1-3]. *Staphylococci* are the principal causative agents accounting for 30% to 50% of wound infections [4]. Preliminary antimicrobial screening has shown activity of methanol extract of latex (FL) on *Staphylococcus albus* and *Staphylococcus aureus* with inhibition zones of 28 mm and 26 mm respectively [5-7].

Investigation of the active constituents from the latex of *F. botryocarpa* centered on alkaloids. Raw fruit latex was extracted with methanol and filtered separating the bioactive filtrate (F2) from the non-bioactive filtered (F1). (F2) was confirmed as predominantly alkaloids by Dragendorff and Mayers test [8]. By means of preparative chromatography three fractions, (1), (2) and (3) were isolated from (F2). These fractions showed strong activity against *Escherichia coli*, *S. aureus* and two bacterial colonies types isolated from an infected folliculitis [9]. This study attempts to identify chemical structures of these alkaloid isolates.

## Materials and Methods

### Sampling

Pricked fruits with latex protruding from petiole and fruit bud were collected in 40 ml polyethylene sampling bottles at Bulolo, PNG.

### Sample preparation

Combined latex, 18 ml was extracted with 50 ml methanol and subject to vibration in a flask shaker (Stuart FS-1) at 200 oscillations per minute for 20 minutes. The process was repeated three times to obtain the primary extract (FL). Insoluble (F1) and soluble (F2) fractions were recovered by gravity filtration using 125 mm and 185 mm using whatman filter papers and concentrated on a BUCHI rotary evaporator under reduced pressure followed by drying under vacuum.

White gummy-like substance, were collected as filtered (F1) and air dried at room condition to solidify. The soluble filtrate (F2) was concentrated on a BUCHI rotary evaporator under reduced pressure followed by vacuum drying. (F2) gave a golden - yellow paste.

1 g of F2 was dissolved in 10 ml MeOH and deposited on a horizontal thin line at the bottom of a preparative silica gel plate. The plate was placed in a chamber containing the solvent, acetone/toluene/ethanol/ammonia (40:40:6:2) mixture [10]. Three spots of  $R_f$  0.26,  $R_f$  0.14 and  $R_f$  0.07 resembling bands developed earlier were ideally developed (blue fluorescence) and marked under UV light at 254 nm. The three fractions were scraped off the glass plate (20 x 20 cm) into separate screw cap conical flask (100 ml). Each fraction was dissolved in Me OH (3 x 30 ml) vibrated at 200 oscillations per minute for 10 minutes and filtered. The filtrates were concentrated in vacuo at 68°C (BUCHI) and further vacuum dried yielding fraction (1) 2.10 mg, (2) 4.20 mg and (3) 6.13 mg.

### Instruments

Melting Point Instrument, Digital 9000 Series, IA9100 230 V (max. 370°C), Clarkson, USA. Melting points were determined by inserting glass capillaries filled with samples to electrothermal melting point apparatus hovels and the values are uncorrected.

NMR spectra were obtained using Varian Unity Inova 300 MHz using VNMRJ software and Bruker Avance spectrometer (600 MHz) equipped with a cryoprobe operated using Top Spin software. CD<sub>3</sub>OD used as reference (1D,  $\delta$ =49.0 ppm (<sup>13</sup>C) and 3.31 ppm (<sup>1</sup>H), whilst 2D  $\delta$ =0.00 (<sup>1</sup>H) ppm).

High resolution mass spectral data were determined on a Bruker BioApex 47 Fourier transform mass spectrometer (FTMS) with an electrospray (ESI) all event sequences were controlled and data reduction performed using Bruker Daltonics XMASS version 7.0.3.0 software.

## Results and Discussion

The three fractions showed distinct separation on the chromatogram evident with M.pt and  $R_f$  values (Table 1). However,  $^1\text{H}$ -NMR spectral information of the three isolates corresponded with literature information of ficuseptine chloride, 2, 3-dihydro-6, 8-bis (4-methoxyphenyl)-, 1H-Indolizinium chloride, (Figure 1).

Structures were determined by physical (M.pt and  $R_f$  values), chemical (phytochemical screening), spectroscopic (1D- $^1\text{H}$  NMR, 2D-HSQC NMR and 2D-HMBC NMR) methods and comparison with literature data (Table 2) [11].

### Structural elucidation

Ficuseptine (2) was obtained as second fraction from preparative chromatography of (F2). Vacuum drying gave orange-like paste (4.20 mg), M.pt 213-215 °C and  $R_f$  0.14 with minor impurities [11].

Proton NMR assignments compared with literature values of ficuseptine chloride and showed exceptional resemblance, (Table 2).

The two methylene protons (2H-1) and (2H-3) resonate as triplets at  $\delta$  3.59 and  $\delta$  4.99 respectively. Electron dense  $\delta$  4.99 (2H-3) on (C-3) depicts the strong electron withdrawing component, quaternary nitrogen ( $=\text{N}=\text{}$ ).

Fraction	M.pt (°C)	$R_f$
1	220-221	0.26
2	213-215	0.14
3	218-220	0.07

Table 1: Physical test results of the three isolates.

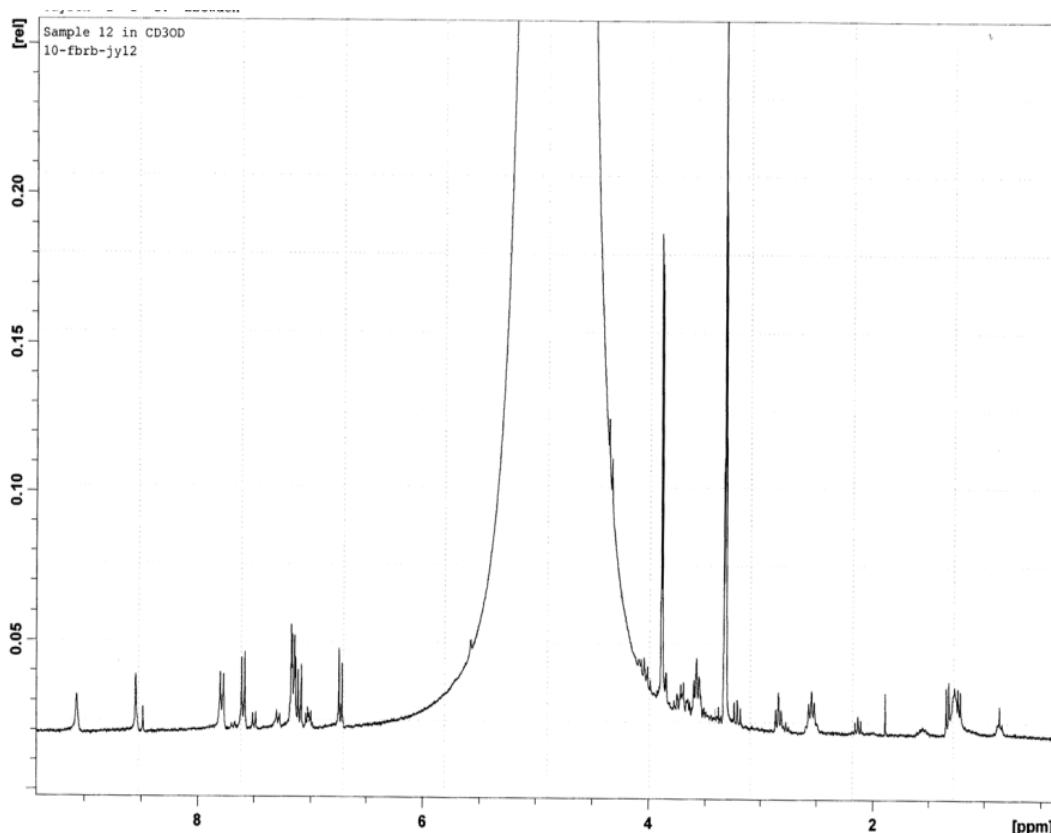

Protons resonating at  $\delta$  3.88 and  $\delta$  3.89 are singlets depicting two methoxy groups. Both  $\delta$  3.88 and  $\delta$  3.89 are *para*-aryls substituents. The methines  $\delta$  9.13 and  $\delta$  8.60 are singlets depicting two lone protons on the indolizinium aryl component.

HMBC correlations of  $\delta$  33.1 from  $\delta$  2.55 ( $^2\text{J}$  2H-2) and  $\delta$  4.99 ( $^3\text{J}$  2H-3),  $\delta$  22.6 from  $\delta$  4.99 ( $^2\text{J}$  2H-3) and  $\delta$  60.9 from  $\delta$  2.55 ( $^3\text{J}$  2H-2) and  $\delta$  3.59 ( $^2\text{J}$  2H-1) is evident the methylene groups comprised in a discrete spin system. The H-C HMBC coupling pattern suggests that the methylene groups are interconnected in a planner system. The high chemical shift of methylene  $\delta$  60.9 (C-3) depicts connection to positively charged electronegative element ( $=\text{N}=\text{}$ ).

Signal at  $\delta$  3.59 ppm shows HMBC correlation to the quaternary acetyl carbon,  $\delta$  155.3 ( $^2\text{J}$  C-9). This signifies the three methylene groups, the quaternary nitrogen and carbon constitutes a five-membered ring system. Chemical shift at  $\delta$  155.3 ppm shows long range correlations from,  $\delta$  8.60 ( $^3\text{J}$  1H-7),  $\delta$  4.99 ( $^3\text{J}$  2H-3) and  $\delta$  9.13 ( $^3\text{J}$  1H-5). More so,  $\delta$  9.13 convinces that its bonding carbon is directly bonded to the quaternary nitrogen; hence, depicting that the five-membered spin system is joined adjacent to an aromatic ring (Figure 2).

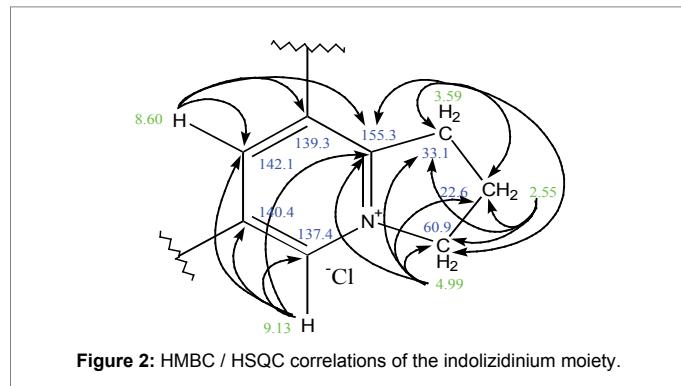

2D NMR correlation analysis of  $^{13}\text{C}$  to  $^1\text{H}$  vice versa via HSQC and HMBC.  $^n\text{J}$  denoting long range correlations beyond  $^3\text{J}$ . Coupling constants  $J$  (Hz) were measured from 1D NMR spectra. Quaternary carbons were derived from correlation analysis of  $^1\text{H}$  to  $^{13}\text{C}$  via HMBC (Table 3).

The two singlets resonating at  $\delta$  8.60 and  $\delta$  9.13 in the aromatic ring is likely in long range  $^1\text{H}$ - $^1\text{H}$  coupling at meta-meta positions. Their correlations to the quaternary  $\delta$  140.4 ( $^2\text{J}_{\text{C},6}$ ) and the presence of

<sup>1</sup> H	$\delta$ (ppm)	
	(2)	Ficuseptine-Cl
1 - (C-H <sub>2</sub> )	3.59	3.54
3 - (C-H <sub>2</sub> )	4.99	5.45
4 -	-	-
5 - (C-H)	9.13	10.09
7- (C-H)	8.60	8.20
4'OMe - (C-H <sub>3</sub> )	3.88	3.80
4'OMe - (C-H <sub>3</sub> )	3.89	3.80

Table 2: <sup>1</sup>H  $\delta$  comparison of (2) with ficuseptine-Cl (4).

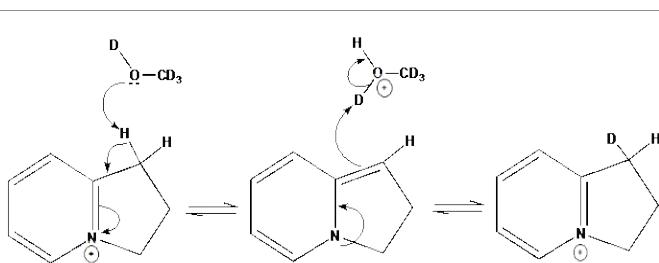

333.1708 is within 1 ppm of the peak observed at 333.1706 (Figure 5).

The compound was established as ficuseptine chloride (2) on the basis of 1D  $^1\text{H}$ -NMR, 2D HSQC and HMBC spectroscopy, MS, melting point (213–215°C) and TLC analysis. Moreover, comparison with literature confirms the compound to be ficuseptine chloride (Figure 1), ruling out possibilities of N-oxides counter ions [11,12] (Figure 6).

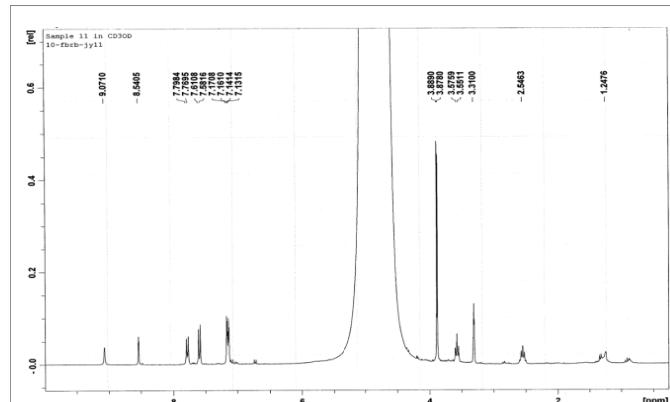

Small quantity of fraction (1) was transferred to a NMR tube and dissolved in 1 ml CD<sub>3</sub>OD and analysed by Varian Mercury 300 MHz NMR at 10 scans. <sup>1</sup>H nmr δ (CD<sub>3</sub>OD): 9.07 (s, 1H-5), 8.54 (s, 1H-7), 7.85 (d, *J*=1.8 Hz, H-2' and H-6'), 7.60 (d, *J*=1.7 Hz, 1H-3" and 1H-5"), 7.15 (dd, 8.4=4.1 Hz, 1H-3', 1H-5', 1H-2" and ,1H-6"), 4.99 (t, *J*=1.6 Hz, 1H-3), 3.89 (s-br, 3H-4"), 3.88 (s-br, 3H-4'), 3.57 (t, *J*=1.8 Hz, 1H-1) and 2.55 (quart, *J*=6.4, 3.1 Hz, 1H-2) ppm.

The compound was identified as ficuseptine (1) on the basis of its  $^1\text{H-NMR}$  spectral comparison with ficuseptinechloride (4) and other literature data ( $R_f$  and melting point) [11,12] (Figure 7).

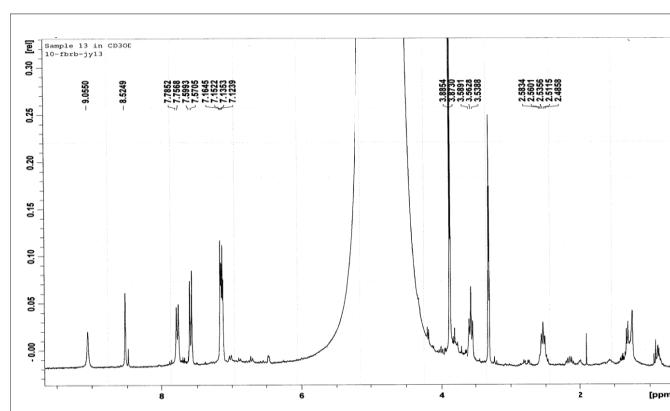

Small quantity of fraction (3) was transferred to a NMR tube and dissolved in 1 ml CD<sub>3</sub>OD and analysed by Varian Mercury 300 MHz NMR at 10 scans. <sup>1</sup>H nmr δ (CD<sub>3</sub>OD): 9.06(s, 1H-5), 8.52 (s, 1H-7),

7.77 (d,  $J=1.8$  Hz, H-2' and H-6'), 7.59 (d,  $J=1.7$  Hz, 1H-3" and 1H-5"), 7.14 (dd,  $8.4=4.1$  Hz, 1H-3', 1H-5', 1H-2" and ,1H-6"), 4.99 (t,  $J=1.6$  Hz, 1H-3), 3.89 (s-br, 3H-4"), 3.87 (s-br, 3H-4'), 3.56 (t,  $J=1.8$  Hz, 1H-1) and 2.54 (quart,  $J=6.4$ , 3.1 Hz, 1H-2) ppm.

The compound was identified as ficuseptine (1) on the basis of its <sup>1</sup>H-NMR spectral comparison with ficuseptinechloride (4) and other literature data ( $R_f$  and melting point) [11,12] (Figure 8).

The compound was identified as ficuseptine (3) on the basis of its <sup>1</sup>H-NMR spectral comparison with ficuseptine chloride (2), ficuseptine (1) and other literature data ( $R_f$  and melting point) [11,12].

## Conclusion

Spectroscopic assessment with  $^1\text{H-NMR}$ ,  $^{13}\text{C-NMR}$ , IR and MS showed all fractions, (1), (2) and (3) to be ficuseptine. Fraction (2) was determined to be ficuseptine chloride based on  $^1\text{H-NMR}$ ,  $^{13}\text{C-NMR}$ , IR and MS data. This is the first time this compound was reported in *F. botryocarpa*. With consistent spectral data fractions (1), (2) and (3) are ficuseptine bearing different anionic components. These ficuseptine derivatives are extremely polar and cationic. It was found that the fruit latex is not active in wet weather [6]. This may indicate that the stable ficuseptine is of bioactive significance vice versa.

More-over there appears an association between the gummy precipitate (F1) and the milky latex (FL) synonymous of the ficuseptine behaving as an emulsifying agent.

The ficuseptine derivatives are reported as chlorides, though the natural anionic form of the three isolated ficuseptine derivatives were

not established. Further work is necessary to isolate the three ficuseptine derivatives in their natural form and confirm the emulsification claim.
