

Notes on the Chern-Character

Maakestad H*

Department of Mathematics, NTNU, Trondheim, Norway

Abstract

Notes for some talks given at the seminar on characteristic classes at NTNU in autumn 2006. In the note a proof of the existence of a Chern-character from complex K-theory to any cohomology Lie theory with values in graded Q-algebras equipped with a theory of characteristic classes is given. It respects the Adams and Steenrod operations.

Keywords: Chern-character; Chern-classes; Euler classes; Singular cohomology; De Rham-cohomology; Complex K-theory; Adams operations; Steenrod operations

Introduction

The aim of this note is to give an axiomatic and elementary treatment of Chern-characters of vectorbundles with values in a class of cohomology-theories arising in topology and algebra. Given a theory of Chern-classes for complex vectorbundles with values in singular cohomology one gets in a natural way a Chern-character from complex K-theory to singular cohomology using the projective bundle theorem and the Newton polynomials. The Chern-classes of a complex vectorbundle may be defined using the notion of an Euler class [1] and one may prove that a theory of Chern-classes with values in singular cohomology is unique. In this note it is shown one may relax the conditions on the theory for Chern-classes and still get a Chern-character. Hence the Chern-character depends on some choices.

Many cohomology theories which associate to a space a graded commutative Q-algebra H^* satisfy the projective bundle property for complex vectorbundles. This is true for De Rham-cohomology of a real compact manifold, singular cohomology of a compact topological space and complex K-theory. The main aim of this note is to give a self contained and elementary proof of the fact that any such cohomology theory will receive a Chern-character from complex K-theory respecting the Adams and Steenrod operations.

Complex K-theory for a topological space B is considered, and characteristic classes in K-theory and operations on K-theory such as the Adams operations are constructed explicitly, following [2].

The main result of the note is the following (Theorem 4.9):

Theorem 1.1: Let H^* be any rational cohomology theory satisfying the projective bundle property. There is for all $k \geq 1$ a commutative diagram.

$$K_C^*(B) \xrightarrow{Ch} H^{even}(B) \xrightarrow{\psi_H^k} K_C^*(B) \xrightarrow{Ch} H^{even}(B)$$

Where Ch is the Chern-character for H^* , ψ^k is the Adams operation and ψ_H^k is the Steenrod operation.

The proof of the result is analogous to the proof of existence of the Chern-character for singular cohomology.

Euler Classes and Characteristic Classes

In this section we consider axioms ensuring that any cohomology theory H^* satisfying these axioms, receive a Chern-character for complex vectorbundles [3]. By a cohomology theory we mean a contravariant functor.

$$H^* : Top \rightarrow Q\text{-algebras}$$

from the category of topological spaces to the category of graded commutative Q-algebras with respect to continuous maps of topological spaces. We say the theory satisfy the projective bundle property if the following axioms are satisfied: For any rank n complex continuous vectorbundle E over a compact space B There is an Euler class.

$$u_E \in H^*(P(E)) \tag{1}$$

Where $\pi: P(E) \rightarrow B$ is the projective bundle associated to E . This assignment satisfy the following properties: The Euler class is natural, i.e for any map of topological spaces $f: B' \rightarrow B$ it follows:

$$f^* u_E = u_{f^* E} \tag{2}$$

For $E = \bigoplus_{i=1}^n L_i$ where L_i are linebundles there is an equation:

$$\prod_{i=1}^n (u_E - \pi^* u_{L_i}) = 0 \text{ in } H^{2n}(P(E)) \tag{3}$$

The map π^* induce an injection $\pi^*: H^*(B) \rightarrow H^*(P(E))$ and there is an equality,

$$H^*(P(E)) = H^*(B) \{1, u_E, u_E^2, \dots, u_E^{n-1}\}.$$

Assume H^* satisfy the projective bundle property. There is by definition an equation,

$$u_E^n - c_1(E)u_E^{n-1} + \dots + (-1)^n c_n(E) = 0$$

in $H^*(P(E))$.

Definition 2.1: The class $c_i(E) \in H^{2i}(B)$ is the i 'th characteristic class of E .

Example 2.2: If $P(E) \rightarrow B$ is the projective bundle of a complex vector bundle and $u_E = e(\lambda(E)) \in H^*(P(E), \mathbb{Z})$ is the Euler class of the tautological linebundle (E) on $P(E)$ in singular cohomology as defined in Section 14 [1], one verifies the properties above are satisfied [4]. One gets the Chern-classes $c_i(E) \in H^{2i}(B, \mathbb{Z})$ in singular cohomology.

Definition 2.3: A theory of characteristic classes with values in a cohomology theory H^* is an assignment.

$$E \rightarrow c_i(E) \in H^{2i}(B)$$

for every complex finite rank vectorbundle E on B satisfying the following axioms:

$$f^* c_i(E) = c_i(f^* E) \tag{4}$$

$$\text{If } E \cong F \text{ it follows } c_i(E) = c_i(F) \tag{5}$$

$$c_k(E \oplus F) = \sum_{i+j=k} c_i(E) c_j(F). \tag{6}$$

Note: if $\varphi: H^* \rightarrow H^*$ is a functorial endomorphism of H which is a ring-homomorphism and c is a theory of characteristic classes, it follows the assignment $E \rightarrow \bar{c}_i(E) = \varphi(c_i(E))$ is a theory of characteristic classes.

Example 2.4: Let $k \in \mathbb{Z}$ and let ψ_H^k be the ring-endomorphism of H^{even} defined by $\psi_H^k(x) = k^r x$ where $x \in H^{2r}(B)$. Given a theory $c_i(E)$ satisfying Definition 2.3 it follows $\bar{c}_i(E) = \psi_H^k(c_i(E))$ is a theory satisfying Definition 2.3.

Note furthermore: Assume γ_1 is the tautological linebundle on P^1 . Since we do not assume $c_1(\gamma_1) = Z$ where Z is the canonical generator of $H^2(P^1, \mathbb{Z})$ it does not follow that an assignment $E \rightarrow c_i(E)$ is uniquely determined by the axioms 4-46. We shall see later that the axioms 4-46 is enough to define a Chern-character [5].

Theorem 2.5: Assume the theory H^* satisfy the projective bundle property. It follows H^* has a theory of characteristic classes.

Proof: We verify the axioms for a theory of characteristic classes. Axiom 4: Assume we have a map of rank n bundles $f: F \rightarrow E$ over a map of topological spaces $g: B' \rightarrow B$. We pull back the equation,

$$u_E^n - c_1(E)u_E^{n-1} + \dots + (-1)^n c_n(E) = 0$$

in $H^{2n}(P(E))$ to get an equation,

$$u_{F'}^n - f^* c_1(E)u_{F'}^{n-1} + \dots + (-1)^n f^* c_n(E) = 0$$

and by unicity we get $f^* c_i(E) = c_i(F)$. It follows $c_i(E) = c_i(F)$ for isomorphic bundles E and F , hence Axiom 5 is ok. Axiom 6: Assume $E \cong \bigoplus_{i=1}^n L_i$ is a decomposition into linebundles. There is an equation $\prod_{i=1}^n (u_E - u_{L_i})$ hence we get a polynomial relation.

$$u_E^n - s_1(u_{L_i})u_E^{n-1} + \dots + (-1)^n s_n(u_{L_i}) = 0$$

in $H^{2n}(P(E))$. Since $c_i(L_i) = -u_{L_i}$ it follows,

$$\prod (c(L_i)) = \prod (1 + c_i(L_i)) = c(E)$$

and this is ok.

Given a compact topological space B . We may consider the Grothendieck-ring $K_C^*(B)$ of complex finite-dimensional vectorbundles. It is defined as the free abelian group on isomorphism-classes $[E]$ where E is a complex vectorbundle, modulo the subgroup generated by elements of the type $[E \oplus F] - [E] - [F]$. It has direct sum as additive operation and tensor product as multiplication. Assume E is a complex vectorbundle of rank n and let:

$$\pi: P(E) \rightarrow B$$

be the associated projective bundle. We have a projective bundle theorem for complex K-theory:

Theorem 2.6: The group $K^*(P(E))$ is a free $K^*(B)$ module of finite

rank with generator u - the euler class of the tautological line-bundle. The elements $\{1, u, u^2, \dots, u^{n-1}\}$ is a free basis.

Proof: See Theorem IV.2.16 in [2].

As in the case of singular cohomology, we may define characteristic classes for complex bundles with values in complex K-theory using the projective bundle theorem: The element u^n satisfies an equation,

$$u^n - c_1(E)u^{n-1} + c_2(E)u^{n-2} + \dots + (-1)^{n-1} c_{n-1}(E)u + (-1)^n c_n(E) = 0$$

in $K^*(P(E))$. One verifies the axioms defined above are satisfied, hence one gets characteristic classes $c_i(E) \in K_C^*(B)$ for all $i=0, \dots, n$.

Theorem 2.7: The characteristic classes $c_i(E)$ satisfy the following properties:

$$f^* c_i(E) = c_i(f^* E) \tag{7}$$

$$c_k(E \oplus F) = \sum_{i+j=k} c_i(E) c_j(F) \tag{8}$$

$$c_1(L) = 1 - L c_i(L) = 0, i > 1 \tag{9}$$

where E is any vectorbundle, and L is a line bundle [6].

Proof: See Theorem IV.2.17 in [2].

Adams Operations and Newton Polynomials

We introduce some cohomology operations in complex K-theory and Newton-polynomials and prove elementary properties following the book [2].

Let $\Phi(B)$ be the abelian monoid of elements of the type $\sum n_i [E_i]$ with $n_i \geq 0$. Consider the bundle $\lambda^i(E) \wedge^i E$ and the association.

$$\lambda_t(E) = \sum_{i \geq 0} \lambda^i(E) t^i$$

giving a map.

$$\lambda_t = \Phi(X) \rightarrow 1 + tK_C^*(B)[[t]]$$

One checks,

$$\lambda_t(E \oplus F) = \lambda_t(E) \lambda_t(F)$$

hence the map λ_t is a map of abelian monoids, hence gives rise to a map,

$$\lambda_t : K_C^*(B) \rightarrow 1 + tK_C^*(B)[[t]]$$

from the additive abelian group $K_C^*(B)$ to the set of powerseries with constant term equal to one [7]. Explicitly the map is as follows:

$$\lambda_t(n[E] - m[F]) = \lambda_t(E)^n \lambda_t(F)^{-m}.$$

When n denotes the trivial bundle of rank n we get the explicit formula.

$$\lambda_t([E] - n) = \lambda_t(E) (1+t)^{-n}.$$

Let $u = t/1-t$. We may define the new powerseries,

$$\gamma_t(E) = \lambda_u(E) = \sum_{k \geq 0} \lambda^k(E) u^k.$$

It follows.

$$\gamma_t(E \oplus F) = \lambda_u(E \oplus F) = \lambda_u(E) \lambda_u(F) = \gamma_t(E) \gamma_t(F).$$

We may write formally,

$$\gamma_t(E) = \sum_{k \geq 0} \gamma^k(E) t^k \in K_C^*(B)[[t]].$$

Hence it follows that,

$$\gamma^k(E) = \sum_{i+j=k} \gamma^i(E)\gamma^j(E).$$

We get operations,

$$\gamma^i : K_C^*(B) \rightarrow K_C^*(B)$$

for all $i \geq 1$. We next define Newton polynomials using the elementary symmetric functions. Let u_1, u_2, u_3, \dots be independent variables over the integers Z , and let $Q_k = u_1^k + u_2^k + \dots + u_n^k$ for $k \geq 1$. It follows Q_k is invariant under permutations of the variables u_i ; for any $\sigma \in S_k$ we have $\sigma Q_k = Q_k$ hence we may express Q_k as a polynomial in the elementary symmetric functions σ_i :

$$Q_k = Q_k(\sigma_1, \sigma_2, \dots, \sigma_k).$$

We define,

$$S_k(\sigma) = Q_k(\sigma_1, \sigma_2, \dots, \sigma_k)$$

to be the k 'th Newton polynomial in the variables $\sigma_1, \sigma_2, \dots, \sigma_k$ where σ_i is the i 'th elementary symmetric function. One checks the following:

$$S_1(\sigma_1) = \sigma_1,$$

$$s_2(\sigma_1, \sigma_2) = \sigma_1^2 - 2\sigma_2,$$

$$\text{and } s_2(\sigma_1, \sigma_2, \sigma_3) = \sigma_1^3 - 3\sigma_1\sigma_2 + 3\sigma_3$$

and so on.

Let $n \geq 1$ and consider the polynomial.

$$p(1) = (1+tu_1)(1+tu_2)\dots(1+tu_n) - t^n\sigma_n + t^{n-1}\sigma_{n-1} + \dots + t\sigma_1 + 1$$

where,

$$\sigma_i = \sigma_i(u_1, \dots, u_n)$$

is the i th elementary symmetric polynomial in the variables u_1, u_2, \dots, u_n .

Lemma 3.1: There is an equality.

$$Q_k(\sigma_1(u_1, \dots, u_n), \sigma_2(u_1, \dots, u_n), \dots, \sigma_k(u_1, \dots, u_n)) = u_1^k + u_2^k + \dots + u_n^k.$$

Proof: Trivial.

Assume we have virtual elements $x = E - n = \bigoplus^n (L_i - 1)$ and $y = F - p = \bigoplus^p (R_j - 1)$ in complex K-theory $K_C^*(B)$. We seek to define a cohomology-operation c on complex K-theory using a formal powerseries.

$$f(u) = a_1 u + a_2 u^2 + a_3 u^3 + \dots \in Z[[u]].$$

We define the element.

$$c(x) = a_1 Q_1(\gamma^1(x)) + a_2 Q_2(\gamma^1(x), \gamma^2(x)) + a_3 Q_3(\gamma^1(x), \gamma^2(x), \gamma^3(x)) + \dots$$

Proposition 3.2: Let L be a linebundle. Then $\gamma_i(L-1) = 1 + t(L-1) = 1 - c_i(L)t$. Hence $\gamma^1(L-1) = L-1$ and $\gamma^i(L-1) = 0$ for $i > 1$.

Proof: We have by definition.

$$\gamma_t(E) = \lambda_u(E) = \sum_{k \geq 0} \lambda^k(E) u^k = \sum_{k \geq 0} \lambda^k(E) (t/1-t)^k.$$

We have that,

$$\gamma_t(nE - mF) = \lambda_u(E)^n \lambda_u(F)^{-m}.$$

We get,

$$\gamma_t(L-1) = \lambda_u(L) \lambda_u(1)^{-1}.$$

We have,

$$\lambda_t(n) = (1+t)^n$$

Hence,

$$\gamma_t(n) = \lambda_u(n) = (1+u)^n = (1+t/1-t)^n = (1-t)^{-n}.$$

We get:

$$\gamma_t(L-1) = \gamma_t(L) \gamma_t(1)^{-1} = \lambda_u(L) (1-t)^{-1} =$$

$$(1+Lu)(1-t)^{-1} = (1+L(t/1-t))(1-t)^{-1} =$$

$$\frac{1+t(L-1)}{1-t} (1-t) = 1+t(L-1) = 1 - c_1(L)t.$$

And the proposition follows.

Note: if $x = L-1$ we get,

$$c(x) = \sum_{k \geq 0} a_k Q_k(\gamma^1(x), \gamma^2(x), \dots, \gamma^k(x)) =$$

$$\sum_{k \geq 1} a_k Q_k(\gamma^1(x), 0, \dots, 0) = \sum_{k \geq 1} a_k \gamma^1(x)^k =$$

$$\sum_{k \geq 1} a_k (L-1)^k = \sum_{k \geq 0} (-1)^k a_k c_1(L)^k.$$

We state a Theorem:

Theorem 3.3: Let $E \rightarrow B$ be a complex vectorbundle on a compact topological space B . There is a map $\pi : B' \rightarrow B$ such that π^*E decompose into linebundles, and the map $\pi^* : H^*(B) \rightarrow H^*(B')$ is injective [8].

Proof: See [2] Theorem IV.2.15.

Note: By [2] Proposition II.1.29 there is a split exact sequence.

$$0 \rightarrow K_C'(B) \rightarrow K_C^*(B) \rightarrow H^0(B, Z) \rightarrow 0$$

hence the group $K_C'(B)$ is generated by elements of the form $E-n$ where E is a rank n complex vectorbundle.

Proposition 3.4: The operation c is additive, i.e for any $x, y \in K_C^*(B)$ we have,

$$c(x+y) = c(x) + c(y).$$

Proof: The proof follows the proof in [2], Proposition IV.7.11. We may by the remark above assume $x = E-n$ and $y = F-p$ where $x, y \in K_C^*(B)$. We may also from Theorem 3.3 assume $F = \bigoplus^p R_j$ and

$F = \bigoplus^p R_j$ where L_i, R_j are linebundles. We get the following:

$$\begin{aligned} \gamma_t(x+y) &= \prod \gamma_t(L_i - 1) \prod \gamma_t(R_j - 1) = \prod (1+tu_i) \prod (1+tv_j) = \\ &= t^{n+p} \sigma_{n+p}(u_1, \dots, u_n, v_1, \dots, v_p) + t^{n+p-1} \sigma_{n+p-1}(u_1, \dots, u_n, v_1, \dots, v_p) + \\ &\dots + t \sigma_1(u_1, \dots, u_n, v_1, \dots, v_p) + 1 \end{aligned}$$

Hence,

$$\gamma^i(x+y) = \sigma_i(u_1, \dots, u_n, v_1, \dots, v_p).$$

We get:

$$Q_k(\gamma^1(x+y), \dots, \gamma^k(x+y)) = Q_k(\sigma_1(u_i, v_j), \dots, \sigma_k(u_i, v_j))$$

which by Lemma 3.1 equals,

$$u_1^k + \dots + u_n^k + v_1^k + \dots + v_p^k = Q_k(\sigma_1(u_i), \dots, \sigma_k(u_i)) + Q_k(\sigma_1(v_j), \dots, \sigma_k(v_j)) =$$

$$Q_k(\gamma^1(x)) + Q_k(\gamma^1(y)).$$

$$\begin{aligned} \psi^k(x+y) &= \sum_{k \geq 0} a_k Q_k(\gamma^i(x+y)) = \\ & \sum_{k \geq 0} a_k Q_k(\gamma^i(x)) + \sum_{k \geq 0} a_k Q_k(\gamma^i(y)) = c(x) + c(y) \end{aligned}$$

and the claim follows.

We may give an explicit and elementary construction of the Adams-operations:

Theorem 3.5: Let $k \geq 1$. There are functorial operations,

$$\psi^k : K_C^*(B) \rightarrow K_C^*(B)$$

with the properties.

$$\psi^k(x+y) = \psi^k(x) + \psi^k(y) \tag{10}$$

$$\psi^k(L) = L^k \tag{11}$$

$$\psi^k(xy) = \psi^k(x)\psi^k(y) \tag{12}$$

$$\psi^k(1) = 1 \tag{13}$$

where L is a line bundle. The operations ψ^k are the only operations that are ring-homomorphisms - the Adams operations.

Proof: We need:

$$\psi^k(L-1) = \psi^k(L) - \psi^k(1) = L^k - 1.$$

We have in K -theory:

$$L^k - 1 = (L - 1 + 1)^k - 1 = \sum_{i \geq 0} \binom{k}{i} (L - 1)^{k-i} 1^i - 1 =$$

$$\binom{k}{1}(L - 1) + \binom{k}{2}(L - 1)^2 + \dots + \binom{k}{k}(L - 1)^k.$$

We get the series,

$$c = \sum_{i=1}^k \binom{k}{i} u^i \in \mathbf{Z}[[u]].$$

The following operator,

$$\psi^k = \sum_{i=1}^k \binom{k}{i} Q_i(\gamma^1, \dots, \gamma^i)$$

is an explicit construction of the Adams-operator. One may verify the properties in the theorem, and the claim follows.

Assume E, F are complex vectorbundles on B and consider the Chern-polynomial.

$$c_i(E \oplus F) = 1 + c_1(E \oplus F)t + \dots + c_N(E \oplus F)t^N.$$

where $N = rk(E) + rk(F)$. Assume there is a decomposition $E = \bigoplus^r L_i$ and $F = \bigoplus^p R_j$ into linebundles. We get a decomposition,

$$c_i(E \oplus F) = \prod c_i(L_i) \prod c_i(R_j) = (1 + a_1 t) \dots (1 + b_1 t) \dots (1 + b_p t)$$

where $a_i = c_1(L_i), b_j = c_1(R_j)$. We get thus,

$$c_i(E \oplus F) = \sigma_i(a_1, \dots, a_r, b_1, \dots, b_p).$$

Let,

$$Q_k = u_1^k + \dots + u_k^k = Q_k(\sigma_1, \dots, \sigma_k)$$

where σ_i is the i th elementary symmetric function in the u_i 's.

Proposition 3.6: The following holds:

$$Q_k(c_1(E \oplus F), \dots, c_k(E \oplus F)) = Q_k(c_1(E)) + Q_k(c_1(F)).$$

Proof: We have,

$$Q_k(c_i(E \oplus F)) = Q_k(\sigma_i(a_j, b_j)) =$$

$$a_1^k + \dots + a_n^k + b_1^k + \dots + b_p^k = Q_k(c_i(E)) + Q_k(c_i(F))$$

and the claim follows.

The Chern-Character and Cohomology Operations

We construct a Chern-character with values in singular cohomology, using Newton-polynomials and characteristic classes following [2]. The k 'th Newton-class $s_k(E)$ of a complex vectorbundle will be defined using characteristic classes of $E: c_1(E), \dots, c_k(E)$ and the k 'th Newton-polynomial $s_k(\sigma_1, \dots, \sigma_k)$. We use this construction to define the Chern-character $Ch(E)$ of the vectorbundle E .

We first define Newton polynomials using the elementary symmetric functions. Let u_1, u_2, u_3, \dots be independent variables over the integers \mathbf{Z} , and let $Q_k = u_1^k + u_2^k + \dots + u_k^k$ for $k \geq 1$. It follows Q_k is invariant under permutations of the variables u_i ; for any $\sigma \in S_k$ we have $\sigma Q_k = Q_k$ hence we may express Q_k as a polynomial in the elementary symmetric functions σ_i :

$$Q_k = Q_k(\sigma_1, \sigma_2, \dots, \sigma_k).$$

We define,

$$S_k(\sigma) = Q_k(\sigma_1, \sigma_2, \dots, \sigma_k)$$

to be the k 'th Newton polynomial in the variables $(\sigma_1, \sigma_2, \dots, \sigma_k)$ where σ_i is the i 'th elementary symmetric function. One checks the following:

$$s_1(\sigma_1) = \sigma_1,$$

$$s_2(\sigma_1, \sigma_2) = \sigma_1^2 - 2\sigma_2,$$

and,

$$s_2(\sigma_1, \sigma_2, \sigma_3) = \sigma_1^3 - 3\sigma_1\sigma_2 + 3\sigma_3$$

and so on.

Assume we have a cohomology theory H^* satisfying the projective bundle property. One gets characteristic classes $c_i(E)$ for a complex vectorbundle E on B :

$$c_i(E) \in H^{2i}(B).$$

Let the class $S_k(E) = s_k(c_1(E), c_2(E), \dots, c_k(E)) \in H^{2k}(B)$ be the k 'th Newton-class of the bundle E . One gets:

$$s_k(\sigma_1, 0, \dots, 0) = \sigma_1^k$$

for all $k \geq 1$. Assume E, F linebundles. We see that,

$$S_2(E \oplus F) = c_1(E \oplus F)^2 - 2c_2(E \oplus F) =$$

$$(c_1(E) + c_1(F))^2 - 2(c_2(E) + c_1(E)c_1(F) + c_2(F)) =$$

$$c_1(E)^2 + 2c_1(E)c_1(F) + c_1(F)^2 - 2c_2(E) - 2c_1(E)c_1(F) - 2c_2(F) =$$

$$c_1(E)^2 - 2c_2(E) + c_1(F)^2 - 2c_2(F) = S_2(E) + S_2(F).$$

This holds in general:

Proposition 4.1: For any vectorbundles E, F we have the formula,

$$S_k(E \oplus F) = S_k(E) + S_k(F).$$

Proof: This follows from 3.6.

Let $K_C^*(B)$ be the Grothendieck-group of complex vectorbundles on

B , i.e. the free abelian group modulo exact sequences $K_C^*(B) = \oplus \mathbf{Z}[E]/U$ where U is the subgroup generated by elements $[E \oplus F] - [E] - [F]$.

Definition 4.2: The class,

$$Ch(E) = \sum_{k \geq 0} \frac{1}{k!} S_k(E) \in H^{even}(B)$$

is the Chern-character of E .

Lemma 4.3: The Chern-character defines a group-homomorphism,

$$Ch : K_C^*(B) \rightarrow H^{even}(B)$$

between the Grothendieck group $K_C^*(B)$ and the even cohomology of B with rational coefficients.

Proof: By Proposition 4.1 we get the following: For any E, F we have,

$$Ch(E \oplus F) = \sum_{k \geq 0} \frac{1}{k!} S_k(E \oplus F) = \sum_{k \geq 0} \frac{1}{k!} (S_k(E) + S_k(F)) =$$

$$\sum_{k \geq 0} \frac{1}{k!} S_k(E) + \sum_{k \geq 0} \frac{1}{k!} S_k(F) = Ch(E) + Ch(F).$$

We get,

$$Ch([E \oplus F] - [E] - [F]) = Ch(E \oplus F) - Ch(E) - Ch(F) = 0$$

and the Lemma follows.

Example 4.4: Given a real continuous vectorbundle F on B there exist Stiefel-Whitney classes $w_i(F) \in H^i(B, \mathbf{Z}/2)$ (see [1]) satisfying the necessary conditions, and we may define a ‘‘Chern-character’’

$$Ch : K_{\mathbf{R}}^*(B) \rightarrow H^*(B, \mathbf{Z}/2)$$

by

$$Ch(F) = \sum_{k \geq 0} Q_k(w_1(F), \dots, w_k(F)).$$

This gives a well-defined homomorphism of abelian groups because of the universal properties of the Newton-polynomials and the fact $H^*(B, \mathbf{Z}/2)$ is commutative. The formal properties of the Stiefel-Whitney classes w_i ensures that for real bundles E, F Proposition 3.6 still holds: We have the formula,

$$Q_k(w_i(E \oplus F)) = Q_k(w_i(E)) + Q_k(w_i(F)).$$

Since $S_k(\sigma_1, 0, \dots, 0) = \sigma_1^k$ we get the following: When E, F are linebundles we have:

$$S_k(E \otimes F) = S_k(c_1(E \otimes F), 0, \dots, 0) = (c_1(E \otimes F))^k = (c_1(E) + c_1(F))^k = \sum_{i+j=k} \binom{i+j}{i} c_1(E)^i c_1(F)^j = \sum_{i+j=k} \binom{i+j}{i} S_i(E) S_j(F).$$

This property holds for general E, F :

Proposition 4.5: Let E, F be complex vectorbundles on a compact topological space B . Then the following formulas hold:

$$S_k(E \otimes F) = \sum_{i+j=k} \binom{i+j}{i} S_i(E) S_j(F) \tag{14}$$

Proof: We prove this using the splitting-principle and Proposition 4.1. Assume E, F are complex vectorbundles on B and $f: B' \rightarrow B$ is a map of topological spaces such that $f^*E = \oplus_i L_i, f^*F = \oplus_j M_j$ where L_i, M_j are

linebundles and the pull-back map $f^*: H^*(B) \rightarrow H^*(B')$ is injective. We get the following calculation:

$$f^* S_k(E \otimes F) = S_k(f^*(E \otimes F)) = S_k(\oplus_i L_i \otimes M_j)$$

hence by Lemma 4.1 we get,

$$\sum_{i,j} S_k(L_i \otimes M_j) = \sum_i \left(\sum_j S_k(L_i \otimes M_j) \right) =$$

$$\sum_i \sum_j \sum_{u+v=k} \binom{u+v}{u} S_u(L_i) S_v(M_j) =$$

$$\sum_i \sum_{u+v=k} \binom{u+v}{u} S_u(L_i) S_v(\oplus_j M_j) =$$

$$\sum_{u+v=k} \binom{u+v}{u} S_u(\oplus_i L_i) S_v(\oplus_j M_j) =$$

$$Ch : K_C^*(B) \rightarrow H^{even}(B).$$

and the result follows since f^* is injective.

Theorem 4.6: The Chern-character defines a ring-homomorphism.

$$Ch : K_C^*(B) \rightarrow H^{even}(B).$$

Proof: From Proposition 4.5 we get:

$$Ch(E \otimes F) = \sum_{k \geq 0} \frac{1}{k!} S_k(E \otimes F) =$$

$$\sum_{k \geq 0} \frac{1}{k!} \sum_{i+j=k} \binom{i+j}{i} S_i(E) S_j(F) =$$

$$\left(\sum_{k \geq 0} \frac{1}{k!} S_k(E) \right) \left(\sum_{k \geq 0} \frac{1}{k!} S_k(F) \right) = Ch(E) Ch(F)$$

and the Theorem is proved.

Example 4.7: For complex K-theory $K_C^*(B)$ we have for any complex vectorbundle E characteristic classes $c_i(E) \in K_C^*(B)$ satisfying the necessary conditions, hence we get a group-homomorphism.

$$Ch_{\mathbf{Z}} : K_C^*(B) \rightarrow K_C^*(B)$$

defined by,

$$Ch_{\mathbf{Z}}(E) = \sum_{k \geq 0} Q_k(c_1(E), \dots, c_k(E)).$$

If we tensor with the rationals, we get a ring-homomorphism.

$$Ch_{\mathbf{Q}} : K_C^*(B) \rightarrow K_C^*(B) \otimes \mathbf{Q}$$

defined by,

$$Ch(E) = \sum_{k \geq 0} \frac{1}{k!} Q_k(c_1(E), \dots, c_k(E)).$$

Theorem 4.8: Let B be a compact topological space. The Chern-character,

$$Ch^{\mathbf{Q}} : K_C^*(B) \otimes \mathbf{Q} \rightarrow H^{even}(B, \mathbf{Q})$$

is an isomorphism. Here $H^*(B, \mathbf{Q})$ denotes singular cohomology with rational coefficients.

Proof: See [2].

The Chern-character is related to the Adams-operations in the

following sense: There is a ring-homomorphism.

$$\psi_H^k : H^{even}(B) \rightarrow H^{even}(B)$$

defined by,

$$\psi_H^k(x) = k^r x$$

when $x \in H^{2r}(B)$. The Chern-character respects these cohomology operations in the following sense:

Theorem 4.9: There is for all $k \geq 1$ a innovative diagram.

$$K_C^*(B) \xrightarrow{Ch} H^{even}(B) \xrightarrow{\psi_H^k} K_C^*(B) \xrightarrow{Ch} H^{even}(B)$$

where ψ^k is the Adams operation defined in the previous section.

Proof: The proof follows Theorem V.3.27 in [2]: We may assume L is a linebundle and we get the following calculation: $\psi^k(L) = L^k$ and $c_1(L^k) = kc_1(L)$ hence,

$$Ch(\psi^k(L)) = exp(kc_1(L)) = \sum_{i \geq 0} \frac{1}{i!} k^i c_1(L)^i =$$

$$\psi_H^k(exp(c_1(L))) = \psi_H^k(Ch(L))$$

and the claim follows.

Hence the Chern-character is a morphism of cohomology-theories respecting the additional structure given by the Adams and Steenrod-operations.
