Abstract

Introduction: Malaria is vector borne disease. Even though there is global step-down in malaria mortality still the African Region still continues to shoulder the heaviest burden: In 2015, this region accounted just about nine in ten malaria cases and deaths world-wide.

Methods: The primary intention of this work was to evaluate four year pattern and trends of malaria morbidity and mortality in Tigray region using backward study system from patients' enrollment and Health Management Information System (HMIS) data. The data was interred and coded to Epi Info and exported to SPSS version 21 for statistics analysis.

Results: A total of 1.5 million malaria cases were analyzed. 78% of the cases were confirmed though liberator where as 22% of the cases diagnosis were made though clinical manifestation without liberator. The most common species of malaria morbidity is *Plasmodium falciparum* which accounts 71% where are the rest were other species. Morbidity in 2014/15 is 33% lower than 2011/12, mortality is 43% lower than 2011/12.

Conclusion: Although elimination and eradication were not possible, reduction of malaria morbidity and mortality were achieved. But still know it needs high-level and uninterrupted political loyalty and changeless attention, deep programmatic attempts in affected arena for eradication and riddance of malaria.

Introduction

Malaria is a very serious public health problem and most important vector borne disease in most developing countries. According to World Health Organization report half of the world population are at risk of malaria with almost all African population [1-3]. Worldwide forward motion in malaria control masks disparities between and within countries. The African Region still continues to shoulder the heaviest burden: In 2015, this one Region accounted for approximately nine in ten malaria cases and deaths world-wide [4].

Local outbreaks are common and the dispersion differs from spot to spot depending on environmental condition and altitude. In Ethiopia malaria is a leading concern since it is one of the primary origins of morbidity and mortality. Despite the actual efforts to control malaria in Ethiopia, the condition has not better principally due to the increasing problems of parasite resistance to the relatively inexpensive anti-malarial drugs, vector resistance to insecticides, low coverage of malaria impeding service [5,6].

Worldwide Malaria mortality has been declined 42% since 2000. In which Africa contributes 49% reduction due to prevention and control measures, 2-3 but in 2010 still 90% malaria death occurred in Africa mostly in under five year age which accounts 24% of the cause of mortality [3,7].

Similarly in 2002 and 2012 Global reports shows 90% and 80% of deaths are from Africa [1,8]. Moreover in 2015 Africa accounted for close to nine in ten malaria cases and deaths worldwide. Malaria is still

headache for African countries even there is disparities between and within state [4].

Materials and Methods

Study area and period

The study was performed in Tigray region that covers an area of 109 square kilometers and its elevation is 2,084 meters above sea level. The region has 18 public hospitals and 170 health centers with total population of 4,316,988 [9-12].

Study design

Retrospective study design from August 2011 up to August 2015 were used to speech act the pattern and direction of malarial morbidity and mortality.

Sample size

All the four year information of public hospitals and health centers of Tigray region were taken.

Data collection procedures and instrument

Data extraction tool was formed to extract information from HMIS registration.

Data analysis

First the data was entered and coded to Epi info version 3.5.4 and exported to analyses in to SPSS version 21 window 7. Data analyses included descriptive statistics was used to describe participants' demographic characteristics and trend of malaria mortality and morbidity.

Data quality management

Data was extracted by statistician from HMIS data of Tigray region with direct oversight.

Ethical clearance

Institution Review Board (IRB) of Aksum University, College of Health Science was examined the code of conduct to guarantee full security of the rights of study subordinates. Pursuing the approval by IRB of Aksum University, IRB of Tigray Region Health bureau also authorized and authoritative letter of co-operation was written to the directorate of health information system. In order to keep privacy of any data obtained, the data aggregation procedure was treated nameless.

Availability of data and material

The data and materials used for analysis and draw conclusion are available at the supplementary data.

Results

Scio-demographic

The study was conducted in all public hospitals and Woreda health offices (170 health center) of Tigray region. An entire of 1.5 million

cases of malaria was taken out from IPD (inpatient department) and OPD HMIS data. From the total participants in the data 1,515,483 (68.8%) were male. No data was leaving out since each was absolute and clear (Table 1).

Pattern of malaria morbidity and mortality

78% of the cases were confirmed though liberator where as 22% of the cases diagnosis were made though clinical manifestation without liberator. The most common species of malaria morbidity is *Plasmodium falciparum* which accounts 71% where are the rest were other species. Similarly 43% of mortality of malaria were diagnosed by clinical without liberator but the rest were diagnosed both clinical and confirmed though liberator. More over 76% of the deaths were related to *P. falciparum* (Figures 1 and 2).

Trend of malaria morbidity and mortality

The trend of malaria morbidity is decreasing every year. Morbidity in 2014/15 is 33% lower than 2011/12, mortality is 43% lower than 2011/12 (Figures 1 and 2).

Discussion

Even though there is no full data and sufficient information of identification of malaria registry in Ethiopia so far, starting from 2011/12 HMIS was initiated. There is also lacking registration of death document and an underestimation of Malaria mortality in Ethiopia. In the absence of certain population enrollment in developing countries like Ethiopia using HMIS is the only accessible frame to detect the

		Age			Total
		<5 years	5-15 years	>15 years	
Sex	Male	98867	178870	765093	1042830
	Female	79244	121753	271656	472653
Total		178111	300623	1036749	1515483

Table 1: Socio-demographic characteristics of participants.

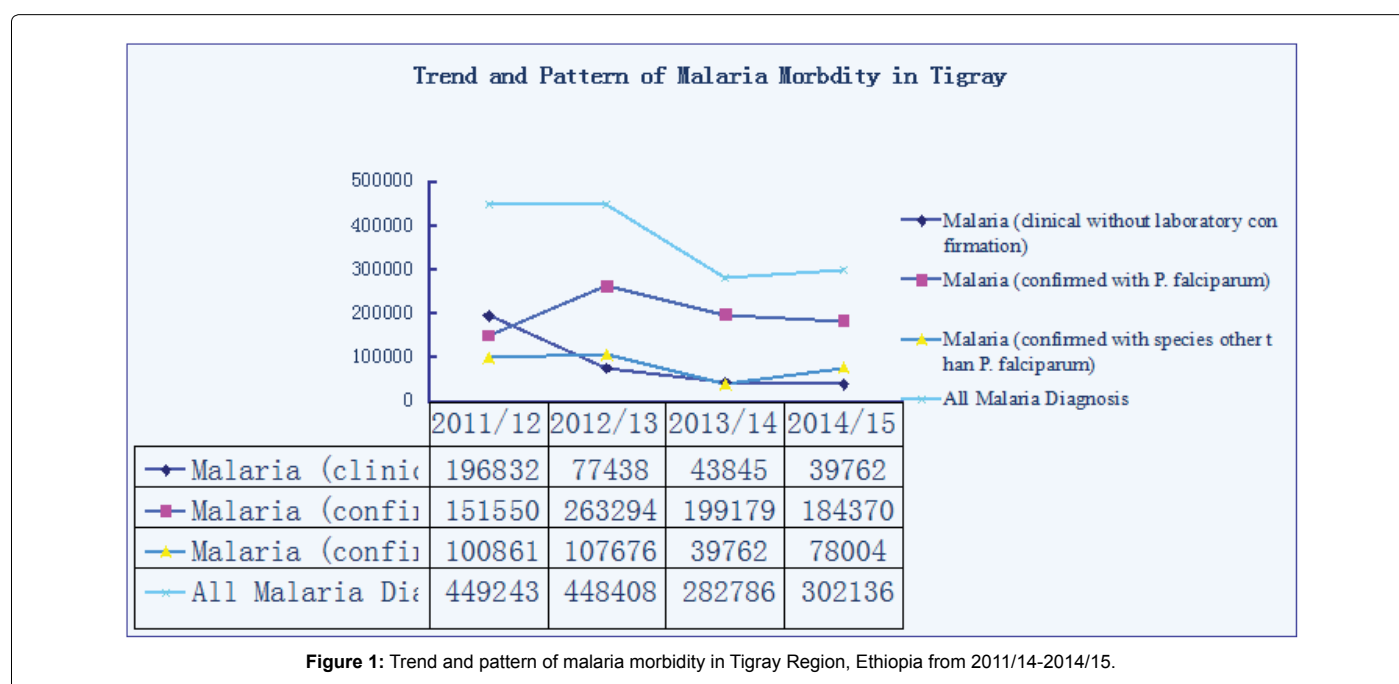

Figure 1: Trend and pattern of malaria morbidity in Tigray Region, Ethiopia from 2011/14-2014/15.

Figure 2: Trend and pattern of malaria mortality in Tigray Region, Ethiopia from 2011/14-2014/15.

direction and pattern of malaria morbidity and mortality in Tigray region [9-11].

Worldwide Malaria mortality has been declined 42% since 2000. In which Africa contributes 49% reduction due to prevention and control measures [2-3]. Similarly this study also shows decline in the four year trend by 43% which indicates some improvement in the bar and control of malaria. Not only prevention and control it also shows improvement in early sensing and control of malaria. This achievement may be resulted from enhanced political engagement, the growth of regional inaugural and improved tool. But still know the Prevention and control strategy did not achieve the World Health Organization (WHO) established the Global Malaria Eradication Programme [4].

The Result also shows *Plasmodium falciparum* is the most common cause of malaria morbidity which is consistent with world health report of 2002. Moreover the trend of *P. falciparum* increase unlike *P. vivax* which is comparable with the study conducted in general hospital of Ethiopia [13]. This may be related with the availability of Rapid Diagnostic Test (RDT). Similarly the study also shows decrease malaria morbidity and mortality with clinical diagnosis without liberator.

The study indicates morbidity of malaria decreased by 33%. This is similar with the study conducted in Mbakong have shown an unsteady, but declining direction over the last seven years with a practically pertinent meaning [14]. This may be achieved due to the National Goals and Targets of the President's Malaria Initiative to reduce malaria mortality in Ethiopia by 50% by the end of a three-year project period [15].

Conclusion

Although elimination and eradication were not possible, reduction of malaria morbidity and mortality were achieved. But still know it needs high-level and sustained political commitment and constant vigilance, intense programmatic efforts in affected areas for eradication and elimination of malaria. More over best strategies should be shared from countries of free malaria.

Limitation of the Study

Data from health facilities are potentially useful for monitoring time trends in the number of malaria cases and deaths but have severe limitations. Analysis was based on routinely collected clinical malaria

data from public health institution. There is a possibility of both under and over reporting of malaria cases due to other febrile illnesses which mimic with malaria. Since retrospective data were used its accuracy and completeness could not be fully verified. Reporting from facilities to districts and from districts to the ministry of health varies in its completeness and timeliness from institution to institution and often does not include non-government facilities.

Acknowledgment

My deepest gratitude goes to Aksum University and TRHB for giving full data and supportive materials and information.

Author Contributions

Hadgu Gerensea conceived and designed the study, analyzed the data and wrote and approved the final manuscript.

Hafta Teklay analysed the data and wrote and approved the final manuscript.
