Abstract
In recent years consumer demand for healthier foods such as seafood products possessing appropriate functional properties and low calories has been increased. In this study, shrimp nuggets having functional properties were manufactured by incorporating commercially available β-glucan and carboxy methyl cellulose (CMC), and were evaluated for sensory, chemical and physical properties. Texture profile analysis (TPA) of par-fried and full fried products showed that shrimp nuggets containing both β-glucan and carboxy methyl cellulose (BG+CMC formulation) had significantly higher springiness, chewiness and cohesiveness than control (p<0.05) and lower hardness and shear force values. Addition of 1% CMC to the batter formulation with 3% β-glucan in core reduced 27% of oil absorption during frying step. Differences in sensory evaluation values between nuggets containing CMC and control were not significant at any particular factors except for the juiciness. Application of BG as a prebiotic soluble fiber and CMC reduces oil uptake during frying, and provides a functional calorie-reduced sea food product with desirable organoleptic properties.

Keywords: Shrimp nuggets; β-glucan; Carboxymethyl cellulose; Functional food; Physical properties; Sensory evaluation

Introduction
Nuggets are small batter-fried paste or piece of chicken, fish or shrimp. Consumption of breaded and battered foods especially seafood, poultry, cheese, and vegetables has become popular over the last few years. Shrimp is one of the world’s most popular consumed shellfish [1]. They are low in saturated fat and high in omega-3 fatty acids. In addition, shrimps are excellent sources of essential amino acids, iron, zinc, copper, and vitamin B-12; however, they are considered as highly perishable commodities. In this regard, several processing methods have been utilized to increase their shelf life [2,3].

Literature
Deep-frying is a preservation method to increase shelf life of foods by reducing the moisture content and microbial population. It also provides a unique combination of flavor and texture properties that improve overall characteristics of the food product [4,5]. Fried shrimp as a fried and easy-to-eat meal, can be a nutritious food with increased shelf life [6,7]. These products are tender and moist on the inside, and have a porous crunchy crust on the surface that enhances their palatability [8,9]. However, during deep-frying a noticeable amount of oil is absorbed in the crust. Now a days, this is often considered to be a negative aspect of deep-fried products that is in contrast with the increasing demand of low-fat foods [10]. Frying affects heat and mass transfer that causes oil moves into the product and water escape from the product into the oil. High temperature causes partial evaporation of water, which moves away from the food and through the surrounding oil. Even though fried foods usually contain high amount of fat, they are still commonly used as popular food products. Global food demand is shifted toward the consumption of low fat and low calories food products to reduce blood cholesterol, hypertension and coronary heart diseases. Several methods are used to reduce oil absorption during deep-fat frying of foods [11]. It is also desirable to minimize moisture loss during frying to maintain textural characteristics of the final fried product [12]. Food coatings proved effective to minimize moisture loss. The effectiveness of coating is explained by its mechanical and barrier properties, which depend on the composition, microstructure and characteristics of the substrate. Among the different approaches to reduce oil absorption during frying, incorporation of hydrocolloids such as cellulose derivatives is suggested [13,14]. A hydrocolloid mixture is usually added to the batter or breading coating to create a barrier against oil absorption either before and/or during frying [15-17]. Carboxymethyl cellulose (CMC) is a water-soluble compound with good film-forming properties [18]. Thermal gelation ability of CMC reduces oil absorption and consequently minimizes calorie intake [19]. The effects of battering and breading in enhancing sensory, physical and chemical properties of various nuggets prepared from shrimp, mackerel, meat and chicken are studied [19-23]. Today, the use of β-glucan due to its functional and nutritional properties is gaining interest. Common oat (Avena sativa) is species of cereal grain mainly grown for its utilization for human consumption. Oat has always been regarded as a health promoting food without clear knowledge of its specific health related effects. It is known for its effects on satiety and retarded absorption of nutrients as well as a deterrent

of various disorders of the gastrointestinal disease [24]. Oat β-glucan (BG) behaves as a prebiotic, and non-digestible food ingredient that affects the host beneficially by selectively stimulating the growth and/or activity of one strain or a limited number of bacterial strains in the colon and thus improves host health [25]. In 1997, the U.S. Food and Drug Administration (FDA) approved a health claim for the use of oat-based foods for lowering the risk of heart disease and passed a unique ruling that allowed oat bran to be registered as the first cholesterol-reducing food at a dosage of 3 g β-glucan per day. Moreover, it is allowed by the FDA to claim health benefits for oat products when 0.75 g of β-glucan is consumed in a serving portion. Oat is a rich and economically important source of soluble dietary fiber. It lowers blood cholesterol [26,27] and post prandial glucose level [28], strengthen immune response and reduces the risk of colon cancer [29]. Prebiotic shrimp nuggets using β-glucan can supply up to 1 g of daily soluble fiber intake [30]; furthermore, when consumed with a diet low saturated fat and cholesterol, it may reduce the risk of heart disease. Although application of prebiotics and reducing oil absorption is known in other foodstuff, it is new for shrimp industry. The main objective of this study was to characterize product and sensory properties of industrial shrimp nuggets supplemented with β-glucan and to demonstrate the effect of carboxymethyl cellulose on the oil absorption of the final product.

Materials and Methods

Preparation of batters and shrimp nuggets

Four different shrimp nuggets were formulated according to Table 1. A reference batter was prepared by mixing egg powder (10.4%) and wheat flour (89.6%). In batter formula, 1% carboxymethyl cellulose (1.3 g) was added. A reference batter was prepared by mixing egg powder (10.4%) and 3% bread crumb of nuggets was replaced with 3% β-glucan (34% purity). The temperature of the water before mixing was 5±10°C Shrimps (Venugopal, 2006). The water: dry mixture ratio was kept at 2:1 (w/v) in all the formulations containing 1% CMC is associated with higher pick-up values [31]. The batter was prepared by mixing all ingredients with 90% water. The batter was preheated before frying. High viscosity in batters replacing the same amount of egg powder. High viscosity in batters containing 1% CMC is associated with higher pick-up values [31]. The batter was preheated before frying. High viscosity in batters containing 1% CMC is associated with higher pick-up values [31]. The batter was preheated before frying. High viscosity in batters containing 1% CMC is associated with higher pick-up values [31]. The batter was preheated before frying. Formulations: Control; CMC Carboxy methyl cellulose 1% of batter; 3% β-glucan in the core of nuggets; 378 CMC+BG Carboxy methyl cellulose 1% of batter and 3% β-glucan in the center (core?) of nuggets.

Frying

Par-fried shrimp nuggets were deep-fried at 180 ± 2°C for 2 min in hydrogenated soy bean oil (Pars Ghoo Edible Oil Mfg. Factory Complex, Tehran, Iran) using a 3-L capacity bench-top deep-fat fryer (Delonghi, ROTOFRITEUSE, Italy). Frying temperature was monitored using a temperature controller (model 689000-01, Eutech Instruments Pte Ltd., Singapore). Fresh oil was preheated (stressed) for 2 h before frying the samples. Shrimp nuggets were deep-fried one by one to minimize temperature fluctuation during frying [34].

Moisture content

Two grams of homogenized shrimp nuggets were placed onto an aluminum dish (Fisher Scientific Co., Fairlawn, NJ) and dispersed evenly across the dish. The moisture content then determined after drying in the oven for 24 h at 105°C [35].

Fat content

Fat content of shrimp nuggets was determined using the Soxhlet extraction method (AOAC, 2005). A 5 g sample was extracted with 10 ml petroleum ether for 16 h at a drip rate of approximately 10 ml/min. Percent fat content was calculated gravimetrically on a dry weight basis.

Warner-Bratzler shear force (WBS)

Warner-Bratzer shear force in par-fried and full fried shrimp nugget samples was quantified using an Instron Universal Testing machine (Instron Corporation, Rochdale, England) equipped with a 500 N load cell (Instron Corporation, Rochdale, England). The samples were chopped into cubes (2×2×2 cm), and then were hooked to the testing machine for the measurement. Each sample was sheared by a V-shaped cutting blade (0.9 mm thickness) at a triangular aperture of 60°C and cross head speed of 60 mm/min [36].

Texture profile analysis (TPA)

Textural properties of nuggets were evaluated using a texture analyzer (Stable Micro System, Model TA.XT 2i/25, UK). Texture profile analysis was performed on central cores of five pieces for each sample pieces (1.5 cm×1.5 cm×1.5 cm), which were compressed twice to 80% of the original height by a compression probe (P 75) at a cross head speed of 2 mm/s. The following parameters were determined: hardness (N/cm²)=maximum force required to compress the sample (H); springiness(cm)=ability of sample to recover its original form after a deformation force was removed (S); cohesiveness=extent to which sample could be deformed prior to rupture (A2/A1,where A1 is the total energy required for first compression and A2 the total energy required for second compression).
required for the second compression); gumminess (N/cm²)=force necessary to disintegrate a semisolid sample for swallowing (Hx cohesiveness); chewiness (N/cm)=work to masticate the sample for swallowing (Sxgumminess) [37].

**Sensory evaluation**

For sensory evaluation, par-fried nuggets were fried and served to 10 trained panelists to assess the color, taste, texture, smell, juiciness, chewiness and overall acceptability of the products using a 9-point hedonic test (1=dislike extremely, 5=neither like nor dislike, and 9=like extremely) [25].

**Experimental design and statistical methods**

All experiments were performed in three replicates. The SPSS Version 19 Statistical software (SPSS Inc, an IBM Company, Chicago, IL, USA) was used for the statistical analyses. Analysis of variance (ANOVA) was performed and significant differences were calculated at 5% significant level. Duncan’s Multiple Range Test was performed where the ANOVA procedure showed significance. Sensory data were analyzed by a non-parametric test using Kruskal-Wallis test.

**Results and Discussion**

**Moisture and fat content**

Moisture and fat content of full fried shrimp nuggets (after 3 min frying) are shown in Figure 1. Application of CMC in batter increased the moisture content of the nuggets significantly (p<0.05), which is associated to the ability of CMC to form gel and retain water during frying. There was an inverse relationship between moisture loss and oil uptake (R²=92.6, p<0.05). Addition of 1% CMC to the batter frying. There was an inverse relationship between moisture loss and associated to the ability of CMC to form gel and retain water during the frying process (due to the lower moisture loss [16]. Thermal gelation or cross-linking of gums promote the formation of a small amount of wide punctures with low capillary pressures, which reduces the entrance of oil into the pores [4]. The fat content in BG shrimp nuggets was 10% lower than control (p<0.05), due to its lower percentages of moisture loss. Compared with the control formulation, BG formula increased the moisture content of nuggets by 5%. An explanation for the lower fat content of BG to control may be due to the protein content of β-glucan accompanied polysaccharide that increased water-binding capacity and reduced the oil absorption [13-16]. Addition of 1% CMC to the batter containing 3% β-glucan in core formulation showed the least oil absorption (27% reduction in fat content) and 11.2% increase in moisture content as compared to the control formula.

Oil and water content of the control and BG+CMC formula were significantly different (p<0.05). Similar results were observed by Chen and Chen (2009) where in fish nuggets containing 1% CMC in batter formulation had the highest moisture contents and the lowest oil contents than control [6].

**Textural analysis**

Warner-Bratzler shear force and texture profile analyses of par-fried and fully fried nuggets indicated that control sample had significantly (p<0.05) highest shear force and hardness degree among all formulations (Tables 3 and 4). On the other hand, shear force and hardness degree of nuggets with CMC+BG formulation were the least (p<0.05), which could be due to their higher moisture content. Decreased hardness and shear force in BG par-fried shrimp nuggets could be associated with the impact of protein to polysaccharide ratio that enhanced water-bindingabilities and resulted in a reduced resistance to compression. During heating, the incorporation of a right ratio of β-glucan to meat protein plays an important role in enhancing binding of water molecules in protein, resulting in softer, juicier protein systems which may be desirable in some food products [6-9]. Morin et al. [9] found that sausages containing β-glucan were softer in texture with increasing levels of, in which β-glucanat 0.8% (w/w) reduced the compression forces of the product [9]. Springiness of CMC+BG nuggets was significantly higher than other products (p<0.05), where as the gumminess of CMC+BG nuggets, which is directly associated with the hardness, was significantly lower (p<0.05). Nuggets containing CMC had significantly higher chewiness and cohesiveness than other formulations (p<0.05), and CMC+BG formula was in the second place.

Thermal gelation property of CMC above its incipient gelation temperature is important in controlling moisture loss [12]. An increased in hardness and shear force of all formula was observed following frying that were due to loss of moisture during the process. Similarly, the springiness of shrimp nuggets was increased in all products after frying process. Like the par-fried shrimp nuggets, hardness and shear force of control formula was significantly higher than the others in fully fried products (p<0.05), which it would be associated with the low moisture content. Changes in the textural properties of the fully-fried shrimp nuggets could be attributed to the physical and chemical changes occurred during the frying process, battering and breadcrumb in particular. Suderman [11] and Loewe [15] correlated textural changes with moisture loss, protein denaturation and starch gelatinization [5-9].
Industrial prebiotic shrimp nuggets using β-glucan with acceptable sensory and textural properties were produced as a functional sea food. In addition, application of carboxymethyl cellulose in shrimp nugget batter was effective to provide a low-calorie product by reducing the oil uptake during the frying process. Functional shrimp nuggets with desirable organoleptic properties offer a valuable alternative for consumers who are seeking low-fat fried products. This product has the potential to be manufactures and marketed as a functional calorie-reduced seafood product. More research is required to evaluate feasibility of large-scale production and the market niches of the formulated shrimp nuggets.

### Conclusions

Industrial prebiotic shrimp nuggets using β-glucan with acceptable sensory and textural properties were produced as a functional sea food. In addition, application of carboxymethyl cellulose in shrimp nugget batter was effective to provide a low-calorie product by reducing the oil uptake during the frying process. Functional shrimp nuggets with desirable organoleptic properties offer a valuable alternative for consumers who are seeking low-fat fried products. This product has the potential to be manufactures and marketed as a functional calorie-reduced seafood product. More research is required to evaluate feasibility of large-scale production and the market niches of the formulated shrimp nuggets.
