Abstract

Background: Today, mental health problem is recognized as a public health problem in developed as well as developing countries [1]. The public health significance of mental and behavioral disorders is demonstrated by the fact that they are among the most important causes of morbidity in primary care settings and produce considerable disability [2].

One of the perceived causes of its high incidence is the low level of mental health literacy* [3] According to Jorm et al. introduced the term 'mental health literacy' and have defined it as 'knowledge and beliefs about mental disorders which aid their recognition, management or prevention'. Mental health literacy consists of several components, including: (a) the ability to recognize specific disorders or different types of psychological distress; (b) knowledge and beliefs about risk factors and causes; (c) knowledge and beliefs about self-help interventions; (d) knowledge and beliefs about professional help available; (e) attitudes which facilitate recognition and appropriate help-seeking; and (f) knowledge of how to seek mental health information [4].

Several studies have shown that knowledge of public attitude to mental illness and its treatment is a vitally important prerequisite to the realization of successful community-based programs. The recognition of mental disorder also depends on a careful evaluation of the norms, beliefs and customs within the individual’s cultural environment [5].

Some studies conducted in Africa have suggested that the experience of stigma by people with mental illness may be common, but there is no information on how widespread negative attitudes to mental illness may be in the community [6].

In Ethiopia where poverty, war, famine, displacement and homelessness are common, mental health is also becoming a major public health problem. However, little is known about the perception of the public regarding mental health problems [1].

This paper is therefore designed to review public knowledge and belief about mental disorders (mental health literacy) in developing countries with particular emphasis on the public knowledge and beliefs about causes and symptoms of mental disorders, public attitude and perception towards people with mental illness and help seeking behaviors. The review will provide important evidences from developing countries which are relevant to introduce the concept of mental health literacy in Ethiopia where mental health policy is absent.

Objectives

The main objective of this paper is to review studies on public knowledge and belief about mental disorders (mental health literacy) in developing countries with particular emphasis on the public knowledge and beliefs about causes and symptoms of mental disorders, public attitude and perception towards people with mental illness and help seeking behaviors, the review has the following specific objectives.

- To review and critically appraise literatures on the knowledge and beliefs about mental disorders in developing countries.
- To fit different experiences and findings together to provide scientific and empirical evidence on the issue of mental health literacy in developing countries.
- Describe the wide range of beliefs and perceptions about mental disorders.

Keywords: Mental health literacy; Mental health; Public; Knowledge; Beliefs and developing countries

Background

Today, mental health problem is recognized as a public health problem in developed as well as developing countries [1]. The public health significance of mental and behavioral disorders is demonstrated by the fact that they are among the most important causes of morbidity in primary care settings and produce considerable disability [2].

One of the perceived causes of its high incidence is the low level of mental health literacy* [3] According to Jorm et al. introduced the term ‘mental health literacy’ and have defined it as ‘knowledge and beliefs about mental disorders which aid their recognition, management or prevention’. Mental health literacy consists of several components, including: (a) the ability to recognize specific disorders or different types of psychological distress; (b) knowledge and beliefs about risk factors and causes; (c) knowledge and beliefs about self-help interventions; (d) knowledge and beliefs about professional help available; (e) attitudes which facilitate recognition and appropriate help-seeking; and (f) knowledge of how to seek mental health information [4].

Several studies have shown that knowledge of public attitude to mental illness and its treatment is a vitally important prerequisite to the realization of successful community-based programs. The recognition of mental disorder also depends on a careful evaluation of the norms, beliefs and customs within the individual’s cultural environment [5].

Some studies conducted in Africa have suggested that the experience of stigma by people with mental illness may be common, but there is no information on how widespread negative attitudes to mental illness may be in the community [6].

In Ethiopia where poverty, war, famine, displacement and homelessness are common, mental health is also becoming a major public health problem. However, little is known about the perception of the public regarding mental health problems [1].

This paper is therefore designed to review public knowledge and belief about mental disorders (mental health literacy) in developing countries with particular emphasis on the public knowledge and beliefs about causes and symptoms of mental disorders, public attitude and perception towards people with mental illness and help seeking behaviors. The review will provide important evidences from developing countries which are relevant to introduce the concept of mental health literacy in Ethiopia where mental health policy is absent.

• Identify gaps in knowledge and beliefs about mental disorders.
• Provide possible recommendations that could serve as a guide
to public health policies, further researches and applications on
the area of mental health literacy.

Methods
A search for peer reviewed journal articles and reports published
after 2005 have been made using MEDLINE data base (pub med),
Google scholar and DOAJ online internet sources. The search used
mental health literacy, mental health, public, knowledge, beliefs and
developing countries separately or in combination as a key word. Some
studies published before 2005 included in the review as they provide
relevant and basic information regarding mental health literacy in
developing countries.

Publications regarding public knowledge and beliefs about mental
disorders (mental health literacy) in developing countries
are selected in the review. However, it is found that only few articles
are comprehensively addressed the issue of mental health literacy in
developing countries.

Therefore, 21 (63 publications were found) studies that addresses
the issue from developing sub Saharan African, south East Asia, and
Middle East countries has been extensively reviewed.

In addition, the review gives particular emphasis on publications
that focused on public knowledge and beliefs about causes and
symptoms of mental disorders, public attitude and perception towards
people with mental illness and help seeking behaviors.

Results
Mental disorders
Mental disorders are diseases that affect cognition, emotion, and
behavioral control and substantially interfere both with the ability
of children to learn and with the ability of adults to function in their
families, at work, and in the broader society [7].

Common mental disorders are depressive and anxiety disorders that
are classified in ICD-10 as: “neurotic, stress-related and somatoform
disorders” and “mood disorders”. The public health significance of
mental and behavioral disorders is demonstrated by the fact that they
are among the most important causes of morbidity in primary care
settings and produce considerable disability [2].

Mental illness affects one in four people at some stage during their
lives. It is estimated that 450 million people are experiencing mental
illness at any one time, most of whom live in developing countries [8].

In any event, it is more likely that poverty and common mental
disorders interact with one another in setting up, in vulnerable
individuals, a vicious cycle of poverty and mental illness. Rather than
actual income, factors such as insecurity, hopelessness, poor physical
health, rapid social change and limited opportunities as a result of less
education may mediate the risk of suffering from mental disorders [2].

Mental health literacy in developing countries
Jorm et al. introduced the term ‘mental health literacy’ and have
defined it as “knowledge and beliefs about mental disorders which aid
their recognition, management or prevention” [4].

The need for the public to have greater mental health literacy is
highlighted by the high lifetime prevalence of mental disorders (up to
50%), which means that virtually everyone will either develop a mental
disorder or have close contact with someone who does [4].

In some developing countries where more than half of the
population may be illiterate the dimensions of mental health literacy
are totally different from those in Western countries [9]. Supernatural
causes of mental disorders are more widely held and traditional sources
of help, such as spiritual healers, are preferred over medical advice for a
range of mental health problems in these countries [9].

One study on gender differences in KAP towards mental illness
reveals that men had better knowledge, beliefs and attitudes towards
mental illness than women. Most of the women were afraid and not
willing to keep friendships with the mentally ill [10].

Knowledge and beliefs about the etiology of mental illness
In one study conducted in Agaro, Ethiopia to assess how mental
health problems perceived by a community, a significant number
of people implicated supernatural powers as causing mental health
problems which is in agreement with other studies conducted in
Ethiopia. Such traditional notions whereby supernatural powers are
attributed to controlling the well being of an individual’s mind are
widespread in all ethnic or religious groups in Ethiopia. Similar results
were also observed in other African studies [1].

In developing countries like India and Morocco a vast majority
of people attributed the schizophrenic symptoms to supernatural
phenomena, drug use, stressful life events, and heredity or personality

As shown in another study conducted in Iraq, the population did
have a fairly reasonable understanding of the etiology of mental illness,
citing genetic factors, negative life events, brain disease and substance
abuse as key causes although God’s punishment and personal weakness
were also viewed as major factors [12]. Evidences from rural Cameroon
shows that Christians (22.7%) had a greater tendency to associate
epilepsy to witchcraft with respect to Muslims (13%). However the
difference was not statistically significant [13].

Regarding gender differences in knowledge and belief about the
etiology of mental illness, findings indicates that more women than
men believed that mental illness is due to possession by evil spirits [10].

Public recognition of mental disorders
Studies from two African [Ethiopia and Nigeria] countries
concerning public recognition of mental disorders have been consulted.
Respondents in study from Ethiopia recognized only overt psychotic
symptoms such as talking to oneself excessive talkativeness and
aggression as signs of mental health problem [1].

Similarly, the most common symptoms proffered by respondents
in the Nigerian study as manifestations of mental illness included
aggression/destructiveness [22.0%], talkativeness [21.2%], eccentric
behavior [16.1%], and wandering [13.3%] [5].

In one study designed to look into the experience of internalized
stigma in mentally ill persons in Tehran, many expressed a concern
about being recognized as having a mental illness causing problems in
their family. Many told that they tried to conceal the fact that they were
mentally ill from their family and from those close to them in order to
avoid problems for themselves, their relatives, and those near to them.
Another issue was the feeling that mentally ill people are considered

KAP: knowledge, attitude and practice.
violent and dangerous—a recurring theme in studies of perceptions of mental illness are believed to be mentally retarded, and to be a public nuisance and dangerous [6]. Similar Nigerian study in Karfi village ascertained that the majority of the respondents harbored negative feelings towards the mentally ill, mainly in the form of fear and avoidance. Literate respondents were seven times more likely to exhibit positive feelings towards the mentally ill as compared to non-literate subjects [OR=7.6, 95% confidence interval = 3.8–15.1] [5].

One study conducted in Uganda showed that a strong interrelationship exists between poverty and mental illness, with stigma playing a crucial mediating role [16].

In another study conducted in Iraq to assess public perception of mental health, around half of respondents thought that mental illness should not get married, and that people with mental disorders should not have children while just under half thought one should avoid all contact with people with mental illness. Just over half thought they could maintain a friendship with someone who had a mental illness, but less than one fifth thought they could marry someone with mental illness [12]. Similar results were reported from Tehran, Iraq, all respondents (n=123) reported that they have experienced feelings of alienation, discrimination, and social withdrawal [17].

Knowledge and attitude of health workers concerning mental disorders

Primary care of mental disorders is crucial in all parts of the world because of the sheer scale of psychiatric morbidity, and especially in sub-Saharan Africa where specialist expertise is very scarce [18]. Literacy survey results from developing countries indicate a lack of basic mental health training associated with a failure to recognize mental health problems, restricted knowledge concerning psychotropic drug therapy, and an inability to visualize practical forms of mental health care which could be introduced at primary care level [19].

In study to assess KAP of primary health care workers, the majority of the sample did however hold some stigmatizing attitudes about depression, [believing that becoming depressed is a way that people with poor stamina deal with life difficulties] which may contribute to the difficulty which some experience in differentiation between unhappiness and clinically significant depressive illness [18]. Several respondents of one Ugandan qualitative study indicated that the psychiatric hospital itself is a major source of stigma [20].

Help seeking behavior

Beliefs about professional help may be very different in developing countries. For example, in Ethiopia traditional sources of help, such as witchcraft, holy water and herbalists were preferred over medical help for a range of mental health problems. By contrast, medical help was overwhelmingly preferred for physical health problems [9]. There was a statistically significant difference between the more educated and the less educated respondents on their preferred place of help for mental health problems [p=0.001] [1].

Psychotherapy is a widely used psychiatric treatment modality in large cities of Pakistan. A significantly greater preference for psychotherapy was noticed among younger, females, more educated and financially independent participants. Similar was the case for respondents who were better aware of this modality and who supported its use as an adjuvant to pharmacotherapy [p<0.05] [12].

People more likely to seek a religious remedy were very religious [OR = 2.32 CI = 1.28–4.237], less educated [illiterate OR = 3.84, CI = 1.033–14.258; primary OR = 2.69, CI = 1.026–7.035; higher secondary OR = 1.86, CI = 1.017–3.40], living in a joint family system [OR = 2.281, CI = 1.121–4.642] and those who had given a religious cause for schizophrenia [OR = 6.56, CI = 3.156–13.630] [21]. One study in India revealed that only few (18%) of the study participants reported that they would visit a psychiatrist if they had an emotional problem but 35 % of the participants agreed to visit a traditional healer for their problem [14].

Limitaions of the Review

Only 18 studies meet the inclusion criteria for the review and it is difficult and at the same time limited to extrapolate the findings to the whole developing world as these studies are subjected to methodological variation and limited scope. Small sample size is another common methodological problem in some of the reviewed studies.

Cultural variability is also another limitation that can affect the implication of the review. Therefore, the findings of this review could give some insights to policy makers and other concerned bodies whose work is related to mental health literacy in Ethiopia, however, the review has limitation to guide policy development and implementation.

Conclusions and Recommendations

From the studies reviewed, it is concluded that there is a low level of mental health literacy in developing countries. Concerning the etiology of mental disorders Supernatural causes of mental disorders are more widely attributed in developing countries. Spiritual sources of help found to be preferred over medical sources for mental health problems in these countries.

Contrary to findings indicating that stigma and discrimination towards mental illness is low in developing countries [6], this review showed that stigma and discrimination towards mental illness is in fact common in these countries. It is also possible to conclude that there is a significant gender difference in knowledge, attitude and beliefs towards mental disorders.

Evidences suggested that Information, education and communication [IEC] should be at the heart of mental health promotion activities which aimed to raise the low level of mental health literacy in developing countries like Ethiopia. These IEC activities need to be incorporated in to countries mental health policy and integrated with primary health care settings.

Future Research

This review highlighted that there have been only few studies that have specifically examined mental health literacy in developing countries and further comprehensive studies need to be conducted.
to understand the level of mental health literacy in developing countries like Ethiopia. It is also found that it is important to give due attention to improve the quality of studies on the area of mental health literacy in developing countries setting with particular emphasis on methodological problems.

Acknowledgement

The authors would like to acknowledge Addis Continental Institute of Public Health and Mekelle University, school of public health for giving this chance and successfully facilitate the whole process of the review.
