Abstract

Background: Physical activity and exercise appear to improve sleep quality. However, the quantitative effects of Tai Chi on sleep quality in the adult population have rarely been examined. We conducted a systematic review and meta-analysis evaluating the effects of Tai Chi on sleep quality in healthy adults and disease populations.

Methods: Medline, Cochrane Central databases, and review of references were searched through July 31, 2013. English-language studies of all designs evaluating Tai Chi’s effect on sleep outcomes in adults were examined. Data were extracted and verified by 2 reviewers. Extracted information included study setting and design, population characteristics, type and duration of interventions, outcomes, risk of bias and main results. Random effect models meta-analysis was used to assess the magnitude of treatment effect when at least 3 trials reported on the same sleep outcomes.

Results: Eleven studies (9 randomized and 2 non-randomized trials) totaling 994 subjects published between 2004 and 2012 were identified. All studies except one reported Pittsburg Sleep Quality Index. Nine randomized trials reported that 1.5 to 3 hour each week for a duration of 6 to 24 weeks of Tai Chi significantly improved sleep quality (Effect Size, 0.89; 95% Confidence Interval [CI], 0.28 to 1.50), in community-dwelling healthy participants and in patients with chronic conditions. Improvement in health outcomes including physical performance, pain reduction, and psychological well-being occurred in the Tai Chi group compared with various controls.

Limitations: Studies were heterogeneous and some trials were lacking in methodological rigor.

Conclusions: Tai Chi significantly improved sleep quality in both healthy adults and patients with chronic health conditions, which suggests that Tai Chi may be considered as an alternative behavioral therapy in the treatment of insomnia. High-quality, well-controlled randomized trials are needed to better inform clinical decisions.

Keywords: Tai Chi; Sleep quality; Quality of Life

Introduction

Adequate sleep is critical for optimum human functioning. Insomnia is a common sleep disorder affecting 30% of adults in the United States, with 10% having insomnia severe enough to cause daytime consequences [1]. Considerable evidence suggests that short-term sleep deprivation can negatively impact an individual’s alertness, mood, attention, and ability to concentrate, whereas long-term sleep deprivation is associated with chronic fatigue, obesity and diabetes, cardiovascular diseases and increased mortality [2-7]. Recent large-scale cohort studies have established a relationship between sleep deprivation and mortality [7,8]. Poor or deprived sleep can result in increased workplace injuries and accidents, reduced work efficiency, poor employee physical and mental health, and an increased economic loss to the society [9-11]. Each year, insomnia associated with lost productivity in the workplace is estimated to cost 63.2 billion U.S. dollars [1].

Treatment approaches to improve sleep quality include both non-pharmacological strategies, such as modifying the sleep environment and improving sleep hygiene, as well as pharmacological strategies. Recent studies have started to explore the effects of mind-body therapies, such as Tai Chi, in addition to conventional treatment approaches to improve sleep quality in various populations.

Tai Chi originated in China as a martial art, focusing on the mind and body as an interconnected system, on breathing, and on keeping a calm state of mind with a goal toward deep states of relaxation. Recent evidence demonstrates the benefits of Tai Chi in treating chronic pain, psychological health, osteoarthritis, rheumatoid arthritis, Parkinson’s disease, cardiovascular health, and overall health related quality of life [12-20]. Tai Chi is becoming increasingly popular in many countries as a form of exercise to promote fitness and well-being. Insomnia may stem from somatized tension or anxiety, and therefore, Tai Chi practice may be a logical therapeutic approach for people seeking to improve their sleep quality. Nevertheless, convincing quantitative evidence to estimate treatment effects has been lacking. No meta-analysis addressing any sleep outcomes with Tai Chi has ever been published. To better inform patients and physicians, we systematically reviewed...
Heterogeneity was estimated with the I² statistic and I² >75% indicates significant heterogeneity.

Statistical heterogeneity was also assessed using the X² test. Statistical analyses were conducted using Stata version SE/11.2 (Stata Corp., College Station, TX).

Results

We reviewed 36 English language abstracts and retrieved 13 full-text articles for detailed evaluation (Figure 1). Two of 13 studies were eliminated for not reporting relevant sleep outcome data. Ultimately, 11 studies that included a total of 994 participants were identified for data abstraction and critical appraisal. We did not search for any unpublished and non-English literature.

Table 1 describes the study design and number of studies and participants for sleep outcomes. Of the 11 studies, there were 9 RCTs, 2 non randomized comparative studies published between 2004 and 2012. They were conducted in 5 countries (USA, Spain, Japan, Vietnam, and Iran). Seven studies were conducted in the US. There were 632 healthy individuals (5 studies) and 362 patients with chronic conditions (6 studies) which included fibromyalgia (3 studies), heart failure (1 study), and cerebrovascular disorder (1 study). Mean age ranged from 21 to 77 years, and 38% of participants were female. Various controls were compared among the 9 RCTs, with 4 RCTs having multiple types of controls. Both non randomized comparative studies from the same US investigators used special recreation as controls among college students. Most studies employed subjective sleep measures, including the PSQI Scale and Epworth Sleepiness Scale (ESS). Only one RCT reported collecting objective sleep measure of Electrocardiogram (ECG)-derived estimation of cardiopulmonary coupling.

Table 2 qualitatively assesses methodology quality for 9 RCTs.
Overall 4 of 9 RCTs were graded good, 1 moderate, and 4 poor quality. Specifically, 6 RCTs reported on randomization sequence generation; 3 described an appropriate allocation concealment method, 5 reported on blinding for outcome assessors. All nine RCTs described withdrawals and dropouts. Dropout rates were moderate with 4 RCTs reporting dropouts 15 to 22%, and that the remaining 5 RCTs reported attrition <15%. One non randomized comparative study reported high dropouts of 23%, while the other did not report data on attrition.

None of the studies reported any other physical activities and exercise other than Tai Chi during study intervention period.

Meta-analysis results

We included 8 of 9 RCTs that provided data on sleep quantitative measures that used the global score of PSQI in the meta-analysis. Figure 2 displays the overall effects of Tai Chi on PSQI. Below, we describe results for studies that provided data for meta-analysis and those excluded from meta-analysis.

Eight of 9 RCTs with 660 participants assessed the effects of Tai Chi on sleep quality in both healthy adults and disease populations using the PSQI questionnaire. We found statistically significant improvements in PSQI with Tai Chi intervention compared with various controls.

Additional outcome measures examined in RCTs included pain, stress, depression, anxiety and quality of life as well as physical function performance. Tai Chi was performed between 6 and 24 weeks (40 to 90 minutes each session, 1 to 3 times per week).

One RCT with 18 participants did not report data on PSQI and therefore, was not included in the meta-analysis [26]. Using objective measures of sleep spectrogram on ECG, this remaining RCT conducted among participants with chronic heart failure showed significantly enhanced sleep stability, walk distance and quality-of-life after a 12 week Yang style Tai Chi intervention that involved a practice frequency of one hour, twice a week [26].

Two non-randomized comparative studies were not included in the meta-analysis due to lack of sufficient quantitative data, and the participants in these studies were healthy college students. These studies reported that a single 50 minutes, twice a week, Chen-style Tai Chi intervention significantly improved sleep quality in healthy college students [31,32].

Other outcomes

RCTs varied considerably in the types of questionnaires used for evaluation of other outcomes including, pain, quality of life, and depression. Four RCTs reported sleep outcomes in detail, of which 3 RCTs reported improvement in sleep outcomes including sleep latency, sleep duration, and use of sleep medications [24,28,29]; 1 RCT found no significant difference [25]. Additional improvements with Tai Chi intervention were observed for the outcome of pain [12,23,24] and functional mobility in 5 RCTs [12,23,26,27,29].

Results were mixed for the outcomes of cognitive ability, depression, and quality-of-life. Significant improvements in cognitive ability with Tai Chi occurred in healthy older adults [27]; however, no significant difference was observed between Tai Chi and control groups in patients with a cerebrovascular disorder [25]. Two RCTs found significant improvement in depression scores [12,25], however 2 other RCTs found no significant difference between Tai Chi and control groups in depression scores [24,28]. Five RCTs evaluated four different quality-of-life measures [12,24-26,29]. Notably, while the overall or physical functioning component of quality-of-life scores improved with Tai Chi intervention versus controls in all 5 RCTs, mental functioning scores showed no difference between groups in 2 RCTs [24,29]. Tai Chi intervention in two non randomized studies showed improvements in outcomes of mood and perceived stress among healthy college students, but had no effect on strength and balance.

Discussion

Tai Chi, a form of low impact mind-body exercise, has spread worldwide over the past three decades. This meta-analysis strengthens a growing body of evidence and updates our previous investigations of the effects of Tai Chi on health outcomes in terms of improved sleep quality.

Specifically, 8 of the 9 RCTs from our quantitative meta-analysis and qualitative evidence synthesis reported that a Tai Chi practice “dose” of 1.5 to 3 hours each week significantly improves overall improvement of sleep quality and enhances functional ability in healthy older adults and patients with chronic conditions. While the subjects with illness may get more benefit than the healthy subjects, we were unable to distinguish significant effects between subjects with and without underlying diseases because only two RCTs reported data on healthy subjects.

Our review is consistent with several other reviews of mind-body therapies for sleep. For example, Sarris and Byrne [33] explored the effects of complementary medicine on the treatment of insomnia. Their review [33] supported evidence that mind-body therapies (Tai Chi and yoga) and manual therapies (acupuncture and acupressure) improve sleep quality. Another review by Irwin, Cole, and Niccassio [34] showed similar robust improvements in sleep quality, sleep latency, and the ability to remain asleep with the use of cognitive-behavioral treatment, relaxation, and behavioral-only treatment in older adults. Indeed, Tai Chi may act in a similar way to cognitive behavioral therapy for insomnia, in that it allows the patient to have a better mind-body connection.

With other forms of exercise, the mind-body connection or control is not always incorporated. For example, compared to a meta-analysis of the effect of exercise training (SMD=0.47, 95% CI 0.08 to 0.86) on improving sleep quality in middle-aged and older adults with sleep problems [35], our study shows that Tai Chi intervention has a better effect (SMD=0.89, 95% CI 0.28 to 1.50). Thus, it appears that Tai Chi has more advantages than regular exercise because of its mind-body attributes.

Although the exact biological mechanisms remain unknown, Tai Chi, a multi-component therapy integrating physical, psychosocial, emotional, spiritual, and behavioral elements, may act through intermediate pathways (e.g., neuroendocrine, immune function, neurochemical, and analgesic) to improve health outcomes [36,37]. It has been hypothesized that mind-body therapies improve sleep outcomes by restoring the homeostatic balance of sympathetic/parasympathetic function by reducing sympathetic activity and stimulating the parasympathetic nervous system. In addition, by focusing on movement or body positioning through controlled breathing and quieting the mind, Tai Chi might stimulate the release of endogenous neurohormones or other health recovery mechanisms [38], and promote deep states of relaxation, thereby proving to be an effective strategy in the treatment of insomnia.

From our review and meta-analysis, we understand that Tai Chi has been useful in treating insomnia and improving sleep quality in both adults and the elderly population, in both healthy people and people with chronic medical problems, as well as in people from different countries. Insomnia causes many negative health and economic outcomes [1-11] and it is prevalent as both a solitary condition and as co-morbidity in a variety of other diseases.

Therefore, it is important to explore an inexpensive and effective way, such as Tai Chi, to treat insomnia and to improve sleep quantity and quality in various populations.

There are several limitations to the available literature base examining the effect of Tai Chi on sleep quality. First, only English language published studies are included in this review. Studies published in other languages should be considered in the future for another systematic review and meta-analysis. Second, the parameters of the study population and intervention are widely variable. There are only 11 studies in this review and these studies vary markedly with regard to recruited populations, control groups, and outcome assessment. They also only examine a short duration of Tai Chi practice (6 to 24 weeks), and as a result the long-term effect of Tai Chi intervention needs to be explored in the future. The eligible studies also include small sample sizes and some of the studies lack a sufficient follow-up period. Third, there are methodology limitations in the reviewed studies, including, lack of allocation concealment and lack of blinding. Fourth, very little information is available on whether mind-body therapies promote objective measures of healthy sleep. For example, none of the studies presented information on objective evaluation of polysomnography in participants.

Even though most of the studies have scientific rigor to support the positive effect of Tai Chi on improving sleep quality, we found that there was a mild to moderate dropout rate from each study. Therefore, we suggest that prior to considering Tai Chi as a treatment option, clinicians discuss with their patients that Tai Chi practice requires discipline and perseverance to achieve the desired outcomes. This is exemplified by the duration and frequency of practice in all eleven studies, which usually require practicing Tai Chi for approximately an hour, two or three times a week and continuing this practice for 12 to 24 weeks. As is the essence of many behavioral therapies, Tai Chi may have profound salutogenic effects on improving sleep quality, and these effects come only with consistent practice.

In conclusion, evidence accrued from 11 clinical trials indicates that Tai Chi appears to be an effective behavioral therapy to treat insomnia and improve sleep quality among healthy subjects and patients with chronic conditions. Future high-quality, well-controlled, longer duration RCTs are needed to better inform clinical decisions about using Tai Chi to treat insomnia and improve sleep quality.
