Abstract

The symptomatic disc displacement of the temporomandibular joint (TMJ) can be treated by many ways, like occlusal splints, physiotherapy, arthrocentesis, arthroscopy and open surgery. TMJ Arthroscopic Lysis and Lavage (ALL) has showed good results in these cases. The aimed of this study were to observe the disc positioning after the procedure and the improvement of pain and mouth opening. 38 (6 men and 32 women) with 54 symptomatic disc displacement were included in this study. The results showed improvement of the disc positioning in 37 TMJ (68.51%), mouth opening in 33 patients (86.84%) and pain in patients 35 patients (92.7%). In conclusion ALL can improve the disc positioning, mouth opening and pain in patients with symptomatic TMJ disc displacement.

Keywords: Arthroscopic lysis; Temporomandibular joint

Introduction

The internal derangement (DI) of the Temporomandibular joint (TMJ), specifically those with disc displacement can be treated by many different kinds, implying that conservative and reversible treatments, for example: intra-oral devices, physiotherapy and medicines and, in some cases, it need surgical treatments like arthrocentesis, arthroscopy and open surgeries, each on with its own rate of effectiveness. This study aimed to observe the disc position after TMJ Arthroscopic lysis and lavage (ALL) through post-procedural MRI and the success rate of pain reduction in jaw function and mouth opening.

Materials and Methods

The patients included in this study were 38 (6 men and 32 women), 54 TMJ, aged 16-55 years, with a mean age of 29.7 years old, treated between January 2013 and October 2014. These patients had limited mouth opening (MIO) >30 mm, pain in jaw function through visual analogic scale (VAS>5, positive for joint load test), magnetic resonance imaging (MRI) showing disc displacement: with reduction (DDWR) and without reduction (DDWoR). The TMJ were classified by Wilkes imaging (MRI) showing disc displacement: with reduction (DDWR) and lavage (ALL) through post-procedural MRI and the success rate of pain reduction in jaw function and mouth opening.

Results

The patients presented with a mean MIO of 21.2 mm and TMJ pain with mean VAS of 7.85 and positive for joint load test. The Wilkes Stages found in the 54 TMJ (38 patients) were II-11 III-23, IV-16, V-4. Of the TMJ the mean VAS improvement index was 86.84% (33 patients - range: 62.7-96.8%), with the smallest and largest opening measurements of 36 mm and 52 mm, respectively, and a mean of 45 mm; the mean improvement index in pain in jaw function was 92.7% (35 patients - range: 71.9-95.3%), with low and high VAS of 0 and 4, respectively, and a mean of 2.3 (Table 1). Control MRI at 6 months post-surgery showed improvement disc positioning in 37 TMJ (68.51%): 8 Wilkes II, 17 Wilkes III, 12 Wilkes IV; the same disc

Discussion

Previous studies have shown positive results for patients after TMJ Arthroscopy Lysis and Lavage (ALL) to improve the MIO and pain, being very stable at long-term [3]. The success rate of ALL for Murakami et al. [4], Friedrich et al. [5], Ohnuki et al. [6] were 91%, 82%, 74% respectively. But these results vary in the literature, suggesting that the success of ALL depends on the Wilkes Stage of the TMJ [7]. In this regard, Bronstein and Merrill [8] reported success rates of 96% for stage II, 83% for stage III, 88% for stage IV, and 63% for stage V. In addition, Smolka and Iizuka [9] described a mean success rate of 86.7%, which varied between 75% and 92.3% according to the TMJ stage. This variability was also noted in the current study and the means obtained were consistent with those in previously published studies with regard to pain reduction and an improved MIO, which were stable during the follow-up period. However, studies about disc positioning after ALL and its correlation with improvement or not of the MIO and pain in function are rare and there are not consensus in the literature to date. Ohnuki et al. [10] had been observed that just 10% of the discs displaced were repositioned after TMJ arthroscopy, and in cases of warped discs the results were worse in follow-up MRI, by the other way showed a improvement in mouth opening and painful symptoms concluding that, the disc function, disc mobility is more important than the disc position. Clark et al. [11] using control MRI evaluations found a new disc positioning closer to the anatomical position, Silva et al. [12] showed at follow-up MRI a rate of 63% better disc position after ALL. Moses e Topper [13] concluded about the new disc position that was not related to disc repositioning, but instead to the mobilization and removal of the adhesions and degenerative inflammatory products. In this study was showed the improvement of anatomic relocation of the disc, but we also can see that in some cases the disc maintained the same position and another few cases your position worsened. Another important observation in this study was that the improvement of the disc positioning was not directly related to the improvement of MIO and pain. In some cases discs remained in the same position or their position worsened, but the patients improved MIO and pain, and other cases that the disc improved your position, patients maintained their initial symptoms. Therefore we agree that disc function (mobility) is more important than its position. The difficulties of the present study was to standardize the sample with only patients with disc displacement and pain and limited opening mouth who were refractory to conservative treatment, and the standardization of the Magnetic Resonance Image (MRI) as well. Further studies should investigate the issue correlating the disc positioning after ALL and its influence on MIO and pain in jaw function.

Conclusions

Arthroscopic Lysis and Lavage (ALL) can improve the articular disc positioning, MIO and reduced pain in jaw function, but the mobility of the disc is more important than its position. Further studies, including a long-term follow-up, are required to consolidate these results.
