Abstract

Ozone is currently being considered as a possible oral antiseptic agent because it is strongly antimicrobial and does not induce microbial resistance. In this study, we examined the effects of ozone exposure on the production of collagen type-1 and inflammatory cytokines in primary human gingival fibroblasts (HGFs) in vitro using enzyme-linked immunosorbent assays. The addition of 0.5 ppm ozone significantly enhanced collagen type-1 production by HGFs within 24 h. Secretion of the pro-inflammatory cytokines interleukin-6 (IL-6) and IL-8 by HGFs treated with lipopolysaccharide decreased when ozone was present in the medium. Together, these results suggest that clinical use of ozone would facilitate the positive balance between HGF-mediated periodontal tissue maintenance and repair and the stimulation of inflammation and tissue degeneration following exposure to microbial pathogens.

Keywords: Ozone; Collagen; Periodontal disease; Human gingival fibroblasts

Introduction

Ozone is currently being considered in dentistry as a possible alternative oral antiseptic agent. Its strong antimicrobial effect without the development of drug resistance has been previously noted in water purification and food preservation techniques [1-3]. In dentistry, ozone has been used either gaseous or aqueous forms for the elimination of caries pathogens, in the disinfection of root canals, and as a rinse for avulsed teeth [4-8]. However, ozone has an unpleasant smell and a short half-life of about 40 min [9]. Ozone also has low water solubility and thus, aqueous ozone formulations provide no long-term sterilization effect. On the other hand, ozone gel (VMC Co., Ltd., Tokyo, Japan), which consists of a glycerin solution containing ozone, has a long-term sterilization effect. The advantages of ozone gel include a 6-month-long sterilization effect, the lack of an unpleasant smell, and no development of bacterial strains manifesting ozone-resistance. In the course of our studies, we have reported the safety evaluation of ozone for the skin and eye, as well as its antimicrobial effects and hemostasis using ozone gel [10-12]. In addition, a number of reports have shown that ozone could cause improvements in periodontal diseases [13-15]. However, the effects of ozone on the functions of the cells involved in periodontal disease have yet to be elucidated [16-19]. Periodontal diseases are caused by a number of cells and cytokine networks, and the contributing factors are complex; therefore, the collection of data from basic research studies using cultured cells is an important tool for understanding disease development and progression. Thus, in this study, we examined the effects of ozone on the production of inflammatory cytokines and type I collagen in human gingival fibroblasts (HGFs) in vitro, and attempted to elucidate the mechanism of action of ozone on periodontal disease.

Materials and Methods

Cell cultures

HGF cells were cultured in Dulbecco’s modified Eagle medium (DMEM, Nissui Pharmaceutical Co., Ltd., Tokyo, Japan) with 10% fetal bovine serum (FBS), 100 units/ml penicillin G, and 100 µg/ml streptomycin at 37°C in a 5% CO₂ and 95% air humidified incubator. HGFs used in this study were obtained from volunteers after appropriate informed consent was obtained. The Ethics Committee of Osaka Dental University approved the study (protocol 110778). HGFs isolated from adherent gingival tissue on the extracted teeth of patients with chronic periodontal were cultured on collagen-coated plates in medium.

Reagents

The following materials and antibodies were purchased: 100 ppm Ozone gel (VMC Co., Ltd.); lipopolysaccharide (LPS) from Porphyromonas gingivalis (P. gingivalis) (InvivoGen, San Diego, CA, USA); anti-Interleukin (IL)-6 and biotinylated anti-IL-6 antibodies (eBiosciences, San Diego, CA, USA); anti-IL-8 and biotinylated anti-IL-8 antibodies (R&D Systems, Minneapolis, MN, USA); biotinylated anti-collagen type I antibody (Rockland, Limerick, PA, USA); and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) (Sigma-Aldrich, St. Louis, MO, USA); BrdU (5-bromo-2’-deoxyuridine) Cell Proliferation Assay kit (Millipore, Billerica, MA, USA).

DNA synthesis and MTI assays

For analysis of DNA synthesis, HGFs (1 × 10⁴/cm²) were cultured in DMEM containing 0.5% FBS (0.5% DMEM) for 24 h. The cells were

then cultured with diluted ozone gel at 0.05, 0.5, and 5 ppm for 2 min, and the culture medium was removed. Then, the cells were washed with 0.5% DMEM and were cultured with 0.5% DMEM containing BrdU for 24 h. The level of DNA synthesis in the cells was determined by measuring BrdU-incorporation using the BrdU Cell Proliferation Assay kit. For MTT assay, cells were cultured with the ozone gel at the above concentrations in DMEM containing 10% FBS (10% DMEM) for 2 min, and the culture medium was removed. Then the cells were cultured with 10% DMEM for 24 h after washing with 10% DMEM. The subsequent procedures were performed as described elsewhere [20].

**Enzyme-linked immunosorbent assays (ELISA)**

To detect cytokine production, HGFs (1 × 10^4/cm^2) were cultured with the ozone gel (0.5 ppm) for 2 min, and then the culture medium was removed. The cells were cultured with *P. gingivalis* LPS (100 ng/ml) for 24 h after washing with 10% DMEM. Then, the culture media were collected, and the cytokine levels were measured using the anti-IL-6 (1 µg/ml) and biotinylated anti-IL-6 (0.6 µg/ml), or anti-IL-8 (2.5 µg/ml) and biotinylated anti-IL-8 (0.2 µg/ml) antibodies. For collagen production, HGFs (1 × 10^4/cm^2) were cultured in DMEM containing 1% FBS (1% DMEM) with the ozone gel (0.5 ppm) for 2 min. The cells were then washed and cultured with 1% DMEM. Levels of collagen type I were measured using the biotinylated anti-collagen type I antibody (0.2 µg/ml). ELISAs was performed as described in the user manual of the CytoSet kits (Biosource International, Camarillo, CA, USA) [21]. The cells for collagen production were lysed with 0.5% TritonX-100, and the amounts of proteins from the cell lysates were measured using a BCA protein assay kit (Pierce Biotechnology, Rockford, IL, USA). Collagen production was normalized to the total protein content of the cell lysates.

**Statistical analysis**

Quantitative data were statistically analyzed using either one-way analysis of variance (ANOVA) followed by a Tukey’s test or a Student’s t-test. Differences were considered to be significant at p<0.05.

**Results**

The effects of ozone on the cell viability of HGFs were examined using an MTT assay (Figure 1). Up to 0.5 ppm dosage, the ozone showed no marked cytotoxicity against HGF, but at 5 ppm, it caused a decrease in cell viability by approximately 20% in comparison with untreated controls. These findings suggested that ozone at this level might be cytotoxic against HGF. Therefore, the conditions of this study were narrowed down to a range within which the ozone did not exhibit cytotoxicity against HGF, and the following experiments were carried out using ozone at 0.5 ppm.

We next evaluated the effects of ozone on the type-I collagen production ability of HGFs, which is directly linked to the regenerative capacity of periodontal tissues (Figure 2). This level of ozone, which promoted cell proliferation in comparison with the controls during the evaluation of cell viability, also enhanced the production of type-I collagen by HGFs by approximately 1.6-fold.

The effects of ozone on the secretion of inflammatory cytokines by HGFs are shown in Figure 3. The production of IL-6 and IL-8 by HGFs was markedly promoted when the latter were placed under the stimulation of LPS from the periodontal pathogenic bacterium *P. gingivalis*, which was known to have a strong inflammation-inducing effect. In contrast, the production of interleukins was markedly suppressed when the stimulation was carried out in the presence of ozone.

**Discussion**

Periodontal diseases, which have been found to be associated with lifestyle-related diseases, are biological responses triggered by complex interactions between the host and periodontal pathogenic bacteria living in the oral cavity, as well as by mechanical stress. In general, the destruction of periodontal tissues and the progression of the damage are due to various cytokines released by cells in the periodontal tissues.

**Figure 1:** Effects of ozone gel on the viability of human gingival fibroblasts.

**Figure 2:** Effects of ozone on collagen type-1 production by human gingival fibroblasts.

**Figure 3:** Effect of ozone on the production of inflammatory cytokines by human gingival fibroblasts.
In conclusion, we demonstrated that ozone increased collagen type-I production and hindered pro-inflammatory cytokine secretion from primary HGFs in vitro. In HGFs, cell growth and DNA synthesis were promoted by 0.5 ppm ozone, as was type-I collagen production. In contrast, this ozone dosage inhibited the production of IL-6 and IL-8 by HGFs that was induced by stimulation using *P. gingivalis* LPS. Together, these results suggest that clinical ozone use would facilitate the positive balance between HGF-mediated periodontal tissue maintenance and repair and the stimulation of inflammation and tissue degeneration following exposure to microbial pathogens.

OMICS International: Publication Benefits & Features

Unique features:
- Increased global visibility of articles through worldwide distribution and indexing
- Showcasing recent research output in a timely and updated manner
- Special issues on the current trends of scientific research

Special features:
- 700 Open Access Journals
- 50,000 Editorial team
- Rapid review process
- Quality and quick editorial, review and publication processing
- Indexing at PubMed (partial), Scopus, EBSCO, Index Copernicus, Google Scholar etc.
- Sharing Option: Social Networking Enabled
- Authors, Reviewers and Editors rewarded with online Scientific Credits
- Better discount for your subsequent articles
