The Effectiveness of Human Validation Process Model Training on Couples’ Marital Satisfaction

Loghman Ebrahimi*
Department of Psychology, University of Zanjan, Zanjan, Iran

Abstract
Current survey has been accomplished in Zanjan City to evaluate the impact of Human Validation Process Model in the increase of Marital Satisfaction level. This research was carried out choosing semi-experimental method (pre-test, post-test, case control study). Statistical society was selected among the volunteer couples referred to consultation centre of Welfare Department of Zanjan City following the relevant recall of researcher. Among a total of 72 people (36 couples), 60 people were randomly selected as a sample group (based on the methodology of this survey). They were placed in two individual groups. 15 experimental couples and 15 case control couples. There was also a drop of 4 people (2 couples per each group), up the end of determined time period. Pre-test Enrich Marital Satisfaction Scale (47 Questions) conducted in both groups (case control and experimental group respectively). Then, therapeutic instructions were trained in eight sessions to each couple according to of Human Validation Process Model. Simultaneously, control case group was placed in waiting list to receive counseling services. After termination all the sessions, both groups undertook post-test questionnaire. Descriptive statistics including (Frequency, mean and variance) and inferential statistics (to assess student's t-test) were applied to analyze dependent and independent samples. Findings suggested that Human Validation Process Model significantly increased Marital Satisfaction level (P<0.001). In addition, the comparative analysis identified a significant difference between men and women in terms of impact of marital satisfaction level following the application this model. So, the author concluded that the impact of this model was more than in women comparing with men P<0.05. human validation process model training increased marital satisfaction.

Keywords: Human validation process model; Marital satisfaction

Introduction
There is much evidence proving that there are serious problems among couples in making love and as well as keeping it. In fact, the problem of dissatisfaction in marital life constitutes the main problem for which the couples decide to refer to counseling centers. Since marital satisfaction is largely associated with solving conflicts which for sure occur in the changing marital life, the necessity of using some solutions for these conflicts which would lead to more and better satisfaction seems quite important and clear. The short term effect of marital satisfaction is couples playing their roles quietly well in regard to each other and also to their children. This would specify the family health and make appropriate grounds for the blooming of their own talents as well as their children’s. The long term marital satisfaction is defined as the entrance of healthy individuals from family into society which will reduce the costs concerning social disorders and incompatibilities and also will result in cultural, social, political and religious growth [1].

There are various definitions for marital satisfaction. According to Ellis [2] one of the best definitions is as follows: the wife and husband have raw feelings of satisfaction and pleasure in their all mutual relationships. Therefore, marital satisfaction is in fact a positive and pleasing vision by couples in every aspect of their marital life. Also, there are different factors which bring about marital satisfaction. Various studies show that the factors regarding individual’s internal growth including characteristic features, feedbacks, beliefs, values and expectations as well as those related to individual’s intra growth including love, intimacy, commitment, passions and sexual relationship, behavioral patterns, family and social issues also affect the degree of marital satisfaction [3]. Also Mollania [4] points to different effects of these factors on the degree of marital satisfaction from a couple to another and from a culture to another culture.

Being aware of this fact that some marital patterns and relationships between couples are in nature those processes which would guide them to separation, and also being aware of the way they can be changed and rebuilt, will help the couples to improve their relationships. All couples experience some levels of incompatibilities, lack of awareness or inability of couples to settle would reduce the stability of relationships and increase separations [5] translated by Firouzabakht. Studies show how deficient and imperfect relations would affect marital satisfaction. In this regard, it have shown that when the communication method and interactional patterns between two individuals are not alike, the chance of dissatisfaction increases. Also, Moradi [6] showed that marital communication skill trainings will increase marital satisfaction among couples. If people obtain self-esteem, self-worth and then be able to make intimate relationships in family structure, they will perform positive and effective behaviors inside the family as well. Positive marital behaviors, could serve as an important information source of advice and solution for marital problems. Remedial and counseling intervenes of parents in order to improve personal relations and quality of marital satisfaction may fall useful for both couples and the behaviors of their children. The rational reasons behind studying the details of marital satisfaction are as follows: perceiving its major role in the family and individual health [7], its importance for the society so...
that successful marriage takes place, giving up offence [8] and the need for developing experimental intervenes for couples in order to prevent or reduce marital stress and divorce [9].

Now a day, lots of various theoretical visions with different approaches are at work to settle marital conflicts and restore the unhealthy communication patterns and therefore improve marital satisfaction of couples. The pattern based on human validation can be referred to as an experimental approach to family issues. Therefore, since on one hand, one of the reasons for marital conflicts, marital dissatisfaction and finally divorce is couples' lack of communication and problem-solving needed skills and their lack of necessary abilities to make a safe, calm and intimate atmosphere, and on the other, lots of desired targets in the pattern based on satir’s process of human validation like provoking feelings, specifying communication patterns in family, improving self-esteem and self-worth and human growth as a whole, compatible to a systematic vision to family, will be probably consistent with a lot of communication and emotional needs of couples, there is a need for practical researches to be done in order to find strategies to promote ill-working communication skills between couples and reduce family conflicts. In this regard, the pattern based on human validation as a part of experimental approach of family therapy is one of those approaches which pays much attention to communication and message delivery within families and present practical strategies and experiences to improve family potencies and the interactions within it. Experimental family therapy focuses on feelings and conflicts. It views awareness and feeling expression as tools for personal and family satisfaction [10]. According to this approach, families are consisted of individuals, and in order to change the family system, the individuals, as a part, should change their behavior [11]. Parsons and Alexander [12] could improve the communication patterns of families under treatment by using family therapy and taking advantage of behavior change strategies. There are a lot of researches proving that a large number of couples suffer from ill-communication patterns before making satisfactory marital relations. Research findings believe that dissatisfied and distracted couples fail to manage conflicts and solve issues and therefore make hard efforts to restore their communication actions. According to Christensen and Shenk [13] if a couple is not able to keep a mutual approach to constructively solve their inevitable differences, the conflict between them will grow. A decrease in the frequency of negative exchanges and an increase in the frequency of positive exchanges while describing conflicts and communication issues in a constructive way can be counted as the target of marital intervening programs [14] Pan [15] and quoted by Dadash et al. [16] applied the satir’s family therapy approach in their research and showed its effectiveness in personal and self-esteem growth as well as an improvement in family performance. The results of this research showed that the quality of mother-daughter relationship was improved after applying family restoration.

According to above-mentioned issues, a need for carrying out the present research in order to improve couples’ relationships and increase the amount of marital satisfaction is felt more than before. The results of the present research, will provide counselors and psychotherapists, especially family therapists, with a clear and applicable perspective on one hand, and on the other, will serve as a practical and experimental guidance to make self-esteem, increase self-worth of family members, clarify and rectify inconsistencies in family massage delivery and their communication patterns and in general human growth, and consequently decrease marital conflicts and enhance marital satisfaction. Furthermore, the results of the study could constitute theoretical and practical bases for reducing marital conflicts, improving communication patterns, and pre and post marriage trainings in order to prevent marital conflicts, which can be used in various educational and therapeutic institutes like counseling centers in universities, welfare organizations, clinics and problem-solving councils. Hence, conducting research on the field of effectiveness of this therapy method on increasing marital satisfaction seems necessary. In the present study efforts have been made to investigate the effectiveness of the training based on the pattern of human validation process on marital satisfaction.

Method

The present study is a quasi-experimental one which has been carried out with a pre-test and post-test design and a control group. The statistical population includes all the couples who, according to a recall made by the researcher, referred to welfare counseling center of Zanjan Province in 2017 in order to solve and improve their marital problems and relationships. The research sample consisted of 30 couples of Zanjan who accepted the recall. After determining and homogenizing the control and experimental groups, the researcher began to teach the pattern of human validation process to the experimental group in a two-month period, consisting of eight sessions of one hour and a half which were held weekly. The control group was held in a waiting status. Independent variables were marriage length, number of children, education. Marital satisfaction was controlled as the dependant variable.

In the present study, Enrich’s marital satisfaction questionnaire was used to measure the marital satisfaction of couples. The questionnaire was designed by Olson et al. [17] and its aim was to measure the strong and weak points in marital relationships and to enrich them [17-19]. The questionnaire was in two formats: one contained 115 questions and the other 125 questions containing 5-item multiple choice questions (from extremely high to extremely low) which was consisted of 12 subscales: ideal perversion, marital satisfaction, personality issues, communication, conflict solving, financial management, leisure activities, sexual relationship, children raising, family and friends, egalitarian roles, religious positioning. The main format would make the subjects tired because of its large amount of questions. Soleimanian [19] in a research “investigating the effect of irrational thinking on marital dissatisfaction” prepared a shortened form of the questionnaire with 47 questions which was used in the present study. The Enrich’s questionnaire has a validity of 1 and a high reliability of 2. The Chronbach’s alpha is reported as 0.92 by Olson [17] 0.94 by Mahdavian and 0.93 by Soleimani [19]. Rasooli [20] has measured the validity coefficient of the questionnaire through Chronbach’s alpha. All the subscales of this questionnaire differentiated satisfied and unsatisfied couples which is a proof for the appropriate reliability of the questionnaire [21]. The content validity of the questionnaire has been affirmed by five psychological professors and family counsel specialists [22]. In the questionnaire, 5 items were designed for each sentence as follows: highly agree, agree, neither agree nor disagree, disagree, highly disagree. The scoring was respectively as 1, 2, 3, 4, 5 for the mentioned items. The maximum score in the questionnaire was 235. The higher a score was, the more marital satisfaction existed. Scores above 70 implied high marital satisfaction among couples and those below 30 indicated high marital dissatisfaction among them.

Selected couples were asked to refer to welfare counseling center of Zanjan Province in a pre-determined time. Enrich’s marital satisfaction test was carried out separately for each couple. After conducting pre-test on both groups (control and experimental), with the active
participation of couples, certain days were determined according to their possible timetable. There were 8 training sessions, once a week for each couple which lasted from 90 to 120 minute (Table 1).

Results

Identifying the effect of training based on human validation pattern. In order to identify the effect of training based on human validation pattern in the experimental group, first the score obtained from marital satisfaction pre-test in both control and experimental group were compared. The satisfaction pre-test was administered to both groups and the obtained results for a whole number of 52 individuals in experimental and control group (as for the experimental group, the mean of pre-test scores was calculated as 98.88, standard deviation as 19.71 and standard error was calculated as 3.87. for the control group

Table 1: The summary of training sessions based on the pattern of human validation process.
the mean of pre-test scores was calculated as 98.73, standard deviation as 20.5 and standard error as 4.02 showed that there was no difference between the two control and experimental groups before training based on human validation pattern and the averages of their pre-test, standard deviation and standard error were almost the same (Table 2).

According to the obtained values, since the calculated T for independent groups (8.81) was bigger than its critical value with df=50 (1.67), the null hypothesis claiming there was a lack of difference between pre-rest and post-test scores is rejected and the alternative hypothesis predicting the effect of using independent variable (training based on the pattern of human validation process) on dependent variable (marital satisfaction) is confirmed. Hence, it can be said that training based on the pattern of human validation process in experimental group will induce significant differences in post-test results of experimental group (Table 3).

Identifying the effect of training based on the pattern of human validation process in men and women the average of score differences in pre-test and post-test of marital satisfaction in after holding sessions for men and women in experimental group with regard to table results, since the T value calculated for correlated groups (repeated measurements for the same group) (9.09) was greater than its critical one with df=12 and α=0.05 (2.17), the null hypothesis predicting lack of difference between men's and women's score in post-test is rejected and the alternative hypothesis claiming upon the difference between the effectiveness of independent variable (training based on the pattern of human validation process) and dependent variable (marital satisfaction) on men and women is confirmed. Therefore, the results showed that while the training was useful in both groups, it was more effective in women. In other words, the training based on the pattern of human validation process has been most effective in women.

**Discussion and Conclusion**

The present study aimed to investigate the effectiveness of the training based on the pattern of human validation process on marital satisfaction enhancement. In the pattern of human validation process, family conflicts and problems stem from communication disorders which in turn stem from low self-esteem and self-worth of family members. Therefore, the present pattern is directed toward increasing self-worth and self-esteem of family members and improving their communication relationships and styles. Hence, teaching this pattern would be greatly effective in increasing marital satisfaction.

A brief look at results of the study shows that those who referred to counseling centers with family problems, though within a wide age range (from 17 to 41) and within a limited marriage length (from few months to 8 years), the most frequent problems existed within the first three years of marriage life (about 70%). This means that, divorce risk

Since the pattern of human validation process takes advantage of a wide range of therapeutic methods and techniques, it can serve as a comprehensive method for treating family problems with regard to the country culture. In the present study, the effectiveness of the pattern has been confirmed by inducing positive changes in the post-test conducted on experimental group. The results of the present study showed that holding training sessions based on this pattern could resolve the problems regarding family members’ relationships, their self-esteem and their self-worth and could strengthen the desired elements of the study. In fact, the ability to communicate, enhance self-esteem and self-worth, express feelings, coordinate verbal and nonverbal messages, increase the awareness about “self” elements as well as ice mount metaphor elements, and also, enhance the potency of individuals to change into a perfect human and to augment responsibility, would all lead to the increase of marital satisfaction within families.
