Lessons Learned from 27 Years Experience and Focus Operating on Symptomatic Conditions of the Spine under Local Anesthesia: The Role and Future of Endoscopic Spine Surgery as a “Disruptive Technique” for Evidenced Based Medicine

Anthony T. Yeung*
Desert Institute for Spine Care, Phoenix, Arizona, USA

Abstract
The Practice of Medicine will always be an art based on science. The human body is more complex and not like a mathematical formula. History has shown that concepts in medicine, judged by “key opinion” leaders, currently depend on scientific publications that affect medical treatment through the medical literature. Strict adherence to Cochrane criteria and old “evidence based” concepts are used for scientific dissemination and publication, but also used for insurance reimbursement in the United States. Health care is becoming more and more supported by government subsidy and payment is dependent on guidelines established by each payer. The ability of innovative and valuable level five expert EBM opinions to get published for dissemination to the scientific community can be difficult for researchers because institutional support or NIH funding is the usual pathway. If there is no institutional support, researchers must pay fees to get their work published in open access Journals. It may be the time to consider “innovative disruption” as a form of evidence based medicine to mitigate the unsustainable increasing cost of health care for spine treatment. Endoscopic spine surgery fits consideration as an innovative disruptive procedure. Patients seeking advice from their chosen physician or health care provider for their physical complaints are for conditions that are based on the Physiology and Patho-anatomy causing their symptoms. In spinal conditions, while most patients are not taken seriously until they complain of “debilitating” pain, symptomatic conditions that can be resolved with tincture of time and/or supportive modalities are supported by allopathic as well as homeopathic and naturopathic physicians. Surgical or invasive procedures are usually reserved for more specific allopathic conditions. These conditions may be due not just pain, but numbness, a change in sensation, weakness, or only intermittent debilitation. The symptoms may also reflect separate and concomitant symptoms that can be confusing when the physician focuses on a single source of the symptom. Extensive experience and perseverance with techniques that work for the clinician is valuable when there is a database large enough to be studied and mined, to demonstrate statistical significance. Such is the case with procedures that can be validated by endoscopic imaging to evaluate, and validate the complaint by the ultimate result: symptom resolution. Traditional radiologic Imaging by itself, however, is inadequate to explain complaints of symptoms that may or may not be debilitating in the physician’s judgment, and the patient may be simply dismissed or prescribed a drug to mitigate the complaint. This has, in many ways, contributed to the myriad of pharma solutions to every symptom complaint in allopathic medicine. A myriad of Naturopathic remedies are also marketed and sold over the counter, supported by millions of symptom sufferers who do not expect insurance reimbursement. There are also allopathic means to diagnose and treat symptomatic conditions in the spine, especially in the lumbar spine that currently garners third party reimbursement. The role and future of endoscopic spine surgery is supported here as an innovative disruption to our current means for scientific validation. Performed expertly and properly, a “warrantee” can be provided.

Introduction
The Practice of Medicine will always be an Art, based on science, but rigid concepts in medicine, judged by key opinion leaders with emphasis on scientific publications, are affecting the medical literature through strict adherence to Cochrane criteria and “evidence based” concepts in order to be accepted for publication and reimbursement. Payers of Insurance re-imbursement does not recognize expert opinion but requires methods proven with level 1 or 2 evidence based studies [1]. Even if the result is warranted, insurance reimbursement to honor contracts that does not meet the arbitrary criteria of the insurance carrier needs reform. The ability of level five expert EBM opinions to get information to the scientific audience can also be difficult for most researchers because they either need institutional or NIH funding, or must pay publishing fees to get their work published by open access Journals. The best level 1 studies are sometimes ignored when the business of spine adversely determines the procedure’s ultimate fate. Chymopapain is one such example [2].

Literture Review
Symptoms of patients in medicine on conditions based on the Physiology and Patho-anatomy causing symptoms, can be endoscopically validated. While most patients are sometimes only taken seriously only when they complain of debilitating pain, symptomatic conditions that can be resolved surgically may only cause numbness, a change in sensation, weakness, or intermittent debilitation [3]. The symptoms may also reflect separate and concomitant symptoms that can be confusing when allopathic physicians only focus on a single

source of the symptoms. Extensive experience and perseverance with techniques that work for the clinician are required to establish a database large enough to be mined and to prove statistical significance. Such is the case with endoscopic imaging and the author’s focus for the past 27 years.

The basics of trauma, tumor, and neuropathy are often present at the same time, and worsen with aging to the extent that it occurs in everyone, and physical immortality is still obviously not attainable [4]. The medical literature also reflects this basic “fact” as truth. Spinal conditions are an example where diagnostic and therapeutic injections can identify symptomatic conditions early, cost effectively, and safely. A few examples of lessons learned with endoscopic identification and treatment of these symptomatic conditions are illustrated with diagnostic and therapeutic injections, correlated with endoscopic imaging of the patho-physiology and path-anatomy of the symptom generator [5]. Some valuable diagnostic procedures are considered “controversial” because even evidence based publications have overt bias by key opinion leaders with different conclusions from published studies. This creates the “controversy” in the literature.

With over 27 years of experience in endoscopic spine surgery endoscopic spine surgeon Anthony Yeung presents his level 5 opinions gleaned from a review of greater than 10,000 of his cases since 1991, documented by his database of results backed by endoscopic images of patho-anatomy. This type of level V validation, together with surgery under local anesthesia allows the patient to provide real time feedback during and after surgery. This can be considered an “innovative disruption” to the usual evidenced based criteria used by payers for insurance reimbursement, but are increasingly accepted by cash patients [6,7].

Endoscopic Imaging is relied on to evaluate and validate the patient’s complaint. Imaging by itself, however, is inadequate to explain complaints of symptoms that may or may not be debilitating in the physician’s judgment, and the patient may be simply dismissed or prescribed a drug to mitigate the complaint [8]. This has, in many ways, contributed to the myriad of pharma solutions to every symptom complaint, causing an opioid crisis when the focus is on pain. A myriad of Naturo-pathic remedies are marketed and not reimbursed by insurance that are sold over the counter. There are allopathic means to explain complaints of symptoms that may or may not be debilitating [9].

Peripheral neuropathy, a complex condition, will be affected by attempts at treating the nerve condition with surgical decompression, but the result may be affected by other non-surgical conditions. A condition known as sympathetic dystrophy, recognized to be a very difficult painful condition to treat, and can be the result of hyperactivity of peripheral nerve from the dorsal and ventral rami [11]. Symptoms in individuals can result from multiple causes. Therefore, diagnostic and therapeutic injections often represent the first step in diagnosis and treatment.

Spinal conditions are an example where diagnostic and therapeutic injections, augmented by discography and foraminal epidoscopy, can identify symptomatic conditions early, cost effectively, and safely. A few examples of lessons learned with endoscopic identification and treatment of these symptomatic conditions are illustrated, correlated with endoscopic imaging of not just the patho-physiology and path-anatomy of the symptom generator, but findings of anomalous anatomy are also discovered [12]. Over 27 years of experience in endoscopic spine surgery is presented. Anthony Yeung’s procedure, philosophy and technique is presented here, reinforced by endoscopic treatment of a complex degenerative condition in the author’s own spine culminating in the need for endoscopic and dynamic stabilization of his spine for degenerative scoliosis, spondylolisthesis, multi-modal disc herniations, lumbar spondylolisthesis, and facet arthrosis [13]. The endoscopic procedures are shown on you tube videos of his surgical procedure performed by his son, Chris Yeung, a traditionally fellow shipped trained spine surgeon who is also endoscopically trained and using his father’s Yeung philosophy and endoscopic technique at www.sciatica.com under the icon "watch real patient procedure videos."

Discussion

Anthony Yeung’s surgery under local anesthesia without sedation
is exhibited in a 3 part staged procedure described in this article. This personal experience with endoscopic surgery consolidated the elder Yeung's philosophy and technique through the successful treatment of his own condition, targeting the pain generator in a staged manner as an alternative to fusion (Figures 1-16).

These 2 examples represent the extremes of clinical conditions that can be treated by endoscopic decompression under local anesthesia. The database contains numerous examples of symptomatic conditions...

Figure 3: Post-op selective endoscopic discectomy™ lateral and axial view.

Note: Surgery was successful in relieving weakness and numbness, but a sharp pain persisted with spinal rotation. Instability and foraminal stenosis was apparent, so the decision to be made was fusion versus dynamic stabilization.

Figure 4: Anthony Yeung chose additional translaminar decompression and Coflex dynamic stabilization over fusion and additional open decompression, recognizing that a fusion, if needed, can be staged. Yeung is now 4 years post op having successfully avoiding fusion.

Figure 5: This PPT slide summarizes the value of Intra-operative Chromo-discography, pre-operative foraminal epiduroscopy, therapeutic transforaminal epidural blocks and Lumbar sympathetic blocks that help predict and treat results in endoscopic spine surgery.

Note: Discography was especially valuable pre-operatively or intraoperatively when a chromophore was added at surgery to vitalize stain degenerative nucleus for as a guide to the amount of disc to remove intradiscally under endoscopic visualization. There were virtually no false positives or negatives, only "false interpretation" in the early stages of endoscopic surgery. Different intradiscal pathologies were identified and treated.

Figure 6: The value of pre-operative evocative discography in identifying the etiology of a painful disc.

Note: When pain was out of proportion to the MRI image, grade IV and V annular tears were identified to leak to the dorsal root ganglion of the exiting nerve. Intradiscal thermal modulation of the tear after removal of interpositional nucleus material brought symptom relief. The length of pain relief was partly dependent on the extent of the tear, the thickness of the remaining annular layers, and the ability of the annulus to heal.

Figure 7: The value of discography in identifying a painful disc causing discogenic pain out of proportion to the image is demonstrated to be caused by irritation of the dorsal root ganglion responsible for pain out of proportion to the MRI image.

Figure 8: Inflammation around the dorsal root ganglion. The addition of an epidural gram as part of the pre-operative work-up also helped identify the patho-anatomy of HNP, central and lateral stenosis.

Figure 9: Incidental discogram identifying communication with the disc with an extruded HNP. Note the needle is cephalad to the disc space.
Note: Other symptomatic conditions were identified and correlated well to ultimately determine the results of foraminal decompression and intradiscal therapy. Examples ranging from painful annular tears to severe spinal and foraminal stenosis are illustrated by these illustrations of symptomatic conditions responding to endoscopic decompression from elderly patients with severe co-morbidities creating a situation of risk vs. benefits.

Figure 10: An epiduralgram can also identify central plus lateral stenosis.

Figure 11: Clinical example #1 Severe central stenosis, and intermittent claudication in an elderly man with high risk surgical morbidities who opted to try transforaminal decompression under local anesthesia.

Figure 12: Case #1 Intra-operative visualization of the decompressed traversing nerve. Surgical specimen of the resected dorsal annulus and the ventral facet after transforaminal removal.

Figure 13: Case #1 Only 1 mm of decompression is needed with ventral decompression under local anesthesia.

Figure 14: Clinical Example #2 Severe discogenic pain from a toxic annular tear in the outer annulus at L5-S1.

Figure 15: An inflammatory membrane containing tiny nerves can be seen in the foramen and epidural space. Occasionally small unmyelinated “sinuvertebral” nerves are visualized. Ablation of these nerves may cause post-op dysesthesia that, if severe, will respond to transforaminal epidural and sympathetic blocks. If no pain is elicited, it can be part of the foraminal ligament or a branches from the dorsal ramus, a sensory nerve.

Figure 16: Sensory nerves in the inflammatory membrane. Ablation of these nerves will decrease discogenic pain.

It is very common for patients to return after years of successful alleviation of their symptomatic condition ranging from 2-20 years following their successful endoscopic surgery. Video examples of endoscopic procedures and playlists of various conditions are demonstrated on you tube at the DISC website www.sciatica.com. The disruptive nature of endoscopic spine surgery, when performed at a
high level by true experienced experts, is one disruptive innovation that should gain interest as part of the future of safe and cost-effective spine care.

Conclusion

Operating under local anesthesia makes endoscopic procedures exceeding safe. It also helps the surgeon use his ever-growing experience to better select and stratify his patients for endoscopic treatment to the extent that the experience allows the surgeon to predict his results as soon as the endoscopic procedure is finished.

The future of endoscopic mediated surgery will be a safe, efficient, and cost-effective method and technique that will bridge the huge gap between naturopathic and nonsurgical remedies favored by and paid for out of pocket by many patients. In the very severe degenerative painful conditions where surgeons are reluctant or unable to offer help because age and co-morbidities, endoscopic procedures will also bridge the gap between pain management and surgically morbid procedures designed for deformity and instability. The “surgeon factor” is critical for any individual to be able to attain the skills and experience in order to be adept at both ends of the spectrum. It will take approximately 5 years for the average trained technician to be skilled and confident enough to adopt endoscopic procedures as a dedicated subspecialty and 10 years to really experience and understand the role and Future of endoscopic philosophy and techniques.
