Abstract

Objective: To evaluate the neuronal toxic effects induced by levodopa and explore the method in which PD can be treated reasonably with levodopa.

Method: The rat models of Parkinson disease (PD) were made by injecting stereotaxically 6-OHDA to right side of the mesencephalic ventral tegmental area (VTA) and substantia nigra pars compacta (SNc). The PD rats were treated intraperitoneally with different dosages (10 mg/kg/d, 50 mg/kg/d, 100 mg/kg/d) and different durations (1 d, 3 d, 5 d, 7 d) of levodopa. At the same time, we observed the injury of substantia nigra by the way of treating PD rats with levodopa for 7 days and then stopped for 7 days. In this study, we used TUNEL to detect the injury of substantia nigra by different doses and durations of levodopa.

Results: The number of substantia nigra apoptosis was increased with the changes of doses and durations of levodopa.

Conclusions: If we use levodopa intermittently or as little as possible, the toxic action of levodopa may be reduced.

Keywords: L-dihydroxy-phenylalanine (L-dopa); Apoptosis

Introduction

Parkinson disease is a common in middle-aged and elderly chronic degenerative diseases of central nervous system. Current clinical practice is still represented by L-dopa dopamine replacement therapy mainly, some researchers [1,2]. Consider L-dopa has a role in neurotoxicity, recent studies [3] suggest that PD may be through apoptosis which caused a common path. L-dopa can increase the PD substantia nigra in rats the role of apoptosis still controversial, whether the role of dose-related has not been reported. The study subjects through the act of observation, the number of substantia nigra cell apoptosis detection, in situ hybridization study of different doses of L-dopa in rat substantia nigra of PD cell toxicity and to explore the role of the toxicity mechanism of gene regulation, so as to clinical more reasonable use of L-dopa treatment of Parkinson's disease and provide experimental basis.

Materials and Methods

Preparation of rat model of PD

Healthy male Wistar rats were purchased from Animal Center of Tongji Medical University. The animals weighed between 180 to 200 g and were 3-months-old. Using improved Thomas methods [4] the production of PD rat model and validate the success model.

Animal selection and grouping

Select the success of PD rat model 100, were randomly divided into two major groups: PD group (n=25), L-dopa group (n=75). L-dopa group of PD rats 8:00 daily intraperitoneal injection of L-dopa injection: (L-dopa injection: L-dopa do powder (Sigma product) dissolved in ethanol containing 0.05% and 0.1% ascorbic acid (Sigma product) water for injection, the preparation of 10 mg/ml, 50 mg/ml, 100 mg/ml in three concentrations of L-dopa injection) To the observation point, according to their points of small doses (10 mg/kg/d), medium (50 mg/kg/d), large (100 mg/kg/d) three group (n=25); PD group was injected in addition to L-dopa from L-dopa injection of other components. Observation point for the 1 d, 3 d, 5 d, 7 d, 14 d, 14 d for the PD dose in each group of rats by intraperitoneal injection of L-dopa injection×7 d, drug 7 d.

Each group per time point 5 PD rats. The control group according to the above point to give L-dopa 100 mg/kg/d.

Outcome Measures

Detected behavior

The control group, L-dopa group were defacto the second day of the scheduled 8:00 behavioral observation study. Intraperitoneal injection of APO 0.5 mg/kg, 40 cm in diameter stainless steel basin Observation of rotational behavior in rats. Measurement of rotation number. Then perfusion fixed, get in the brain, paraffin-embedded.

Apoptosis detect (TUNEL method)

Seaton by ways apoptotic cells in the substantia nigra line detection [5].

Image Analysis

The use of multimedia BUAA Photo True Color pathological analysis system for image analysis of biopsy. All the slices are of uniform magnification (100x), under the same light intensity analysis, each case of apoptosis, in situ hybridization for the immediate vicinity of the three sections, the substantia nigra area to observe the same size, measure the window for 26244 μm², analysis of indicators:

positive number density, the positive surface density. All data analysis
system are automatically calculated and printed.

Statistical Methods
All data are expressed as mean ± standard deviation (X ± SD)
said that the use of mathematical statistics Oxstat group process
is complete, the group paired data test of significance (ANOVA).

Results
L-dopa-induced cell apoptosis in the outcome of PD in rats
PD group the number of nigral apoptosis gradually decreased
with time; small dose group 1 d, 3 d little change; 5 d, 7 d decline, 14
d group the lowest, with the exception of 14 d, the other the defacto
with the PD group was no significant difference; Medium Dose Group
apoptosis 14 d<1 d d<3 d<7 d<5 d, 5 d highest point of time than the
PD group, low-dose group was significantly higher; the number of
high-dose group apoptosis 14 d<7 d<5 d<3 d<1 d, 1 d highest the defacto
high-dose group than the small number of apoptotic, middle dose
group and PD group was significantly increased (Table 1).

Discussion
(a) In L-dopa dopamine replacement therapy are the main drug.
its side effects are also very obvious that the latest studies suggest
that L-dopa has resulted in the substantia nigra apoptosis [6,7]. High-dose
group the peak of apoptosis in the 1 d, 3 d ~ 7 d decreased 7 days
after discontinuation of treatment, decreased significantly close to
the control of water found in this study low-dose L-dopa group apoptotic
with the control group no significant difference; Medium dose group
number of apoptotic nigral with L-dopa treatment time increases,
the peak appears in the 5 days, and 7 days after discontinuation of
apoptotic down to the level of the control group level; at the same time
point in each group the number of substantia nigra cell apoptosis is
also with the L-dopa dose increased.

The above results indicate that cell apoptosis from the perspective
of L-dopa with proven neurotoxic effects, apoptosis involved in the
L-dopa on the injury and the role of stromal cells. L-dopa can accelerate
apoptosis in the substantia nigra. L-dopa nerve toxicity with the drug
dose, drug use increased with increasing time. L-dopa treatment in
each group 7 days after discontinuation of treatment, apoptosis
was significantly reduced and shows that L-dopa neurotoxicity are
reversible, drug can reduce the toxic effects.

(b) L-dopa neurotoxicity is not self-caused, but its decomposition
products arising from oxidative metabolism [8]: (1) L-dopa oxidation
can generate its own superoxide dismutase, hydrogen peroxide,
hydroxyl radical, quinones, semiquinone radicals, etc., can be lead
to PC12 cell apoptosis or death, even if L-dopa to DA conversion is
inhibited, the toxic effects still exist and can be inhibited antioxidants
[7]. (2) Inhibition of substantia nigra mitochondrial enzyme complex
I (Complex I) [9]. (3) DNA can cause substantial damage to nerve
cells [10]. This experiment found that L-dopa in rat substantia nigra
oral L-dopa does not nigrostriatum of normal damage, but it can add
to have damage in the substantia nigra striatal damage, but there is
no sufficient basis for the clinical experimental evidence confirmed
that L-dopa to dopamine neurons have residual damage, probably
because the substantia nigra of normal rat striatum system perfect
free radical scavenging system, a reasonable distribution of iron ions
are reasonable, the generation of free radicals and metabolism are
reasonable, and metabolism of toxic decomposition product has a certain
ability to carry out rapid metabolism.

About PD treatment, researchers have advocated the early use of
dopamine receptor agonist, but clinical data show that only 30% of
patients effectively, and the existence of consciousness vague, visual
hallucination, hemianopsia such as side effects, so the traditional
DA replacement therapy is still the main means of treatment of PD
The key is how to reach best effect and least side-effects. Through
this experiment, we believe that: (1) Early PD, in order to reduce
the decomposition products from DA-induced neurotoxicity may
be taken monoamine oxidase inhibitors or drugs such as anti-free
radical: Amphetamine-Propargyl, vitamin E, vitamin A such that
DATATOP program (depenyl and tocopherol antioxidation therapy
of parkinsonism). (2) L-dopa treatment are advised to start small
doses, steady and high-dose medication advocates multiple use
and minimize the dose of each medication, medication to extend
the time interval. (3) L-dopa controlled release tablets containing
simultaneously inhibit L-dopa, DA decomposition of pharmaceutical
ingredients is an ideal method of treatment, researchers have found
that continuous DA stimulation of long-term treatment has less
complications than fluctuation in long-term treatment.
