Abstract

In this note we define a notion of Courant pair as a Courant algebra over the Lie algebra of linear derivations on an associative algebra. We study formal deformations of Courant pairs by constructing a cohomology bicomplex with coefficients in a module from the cochain complexes defining Hochschild cohomology and Leibniz cohomology.

Keywords: Courant algebra; Leibniz algebra; Lie algebra; Cohomology of associative; Lie and Leibniz algebras

Introduction

The aim of this article is to define a notion of Courant pair as a Courant algebra over the Lie algebra \( \text{Der} (A) \) of linear derivations on an associative algebra \( A \) and describe a one parameter formal deformation theory of Courant pairs. We construct a cohomology bicomplex using the Hochschlind cohomology for associative algebras and cohomology of Leibniz algebras respectively.

The notion of Courant algebras was defined by H. Bursztyn and coauthors [1] in the context of reduction of Courant algebroids and generalized complex structures. It is used to interpret the moment map in symplectic geometry as an object which controls an extended part of the action of Courant algebras on Courant algebroids. By definition, a Courant algebra over a Lie algebra \( g \) is a Leibniz algebra \( L \) equipped with a Leibniz algebra homomorphism to the Lie algebra \( g \). One special case of this type of algebras is an exact Courant algebra where the Leibniz algebra homomorphism is a surjective map onto \( g \) and the kernel of the map is an abelian Lie algebra \([1,2]\). In fact, any Leibniz algebra \( L \) can be viewed as an exact Courant algebra over the associated Lie algebra \( L_{\text{ab}} \) by taking the quotient linear space \( L/L^{[\infty]} \), where \( L^{[\infty]} \) is also called the Leibniz kernel of \( L \) is the module generated by elements of the form \( [\{x,y\}] \) for \( x \in L \). The notion of Leibniz algebras were introduced by Bloh [3] under the name \( D \)-algebras and it is rediscovered by J.-L. Loday in connection with cyclic homology and Hochschild homology of matrix algebras [4,5]. The \( (\text{co}) \) homology with coefficients in a representation associated to Leibniz algebras has been developed in ref. [6]. Any Lie algebra is also a Leibniz algebra, as in the presence of skew symmetry of the Lie bracket the Jacobi identity for the bracket is equivalent to the Leibniz identity. It is also important to note that a Courant algebra can be viewed as a model to get Leibniz algebras in the form of hemisemidirect products (as introduced in ref. [7]) by starting with a Lie algebra \( g \) and a \( g \)-modules. One of the Lie algebras mostly encountered in geometry or in mathematical physics is the Lie algebra \( \chi (M) \) of smooth vector fields on a smooth manifold \( M \). This Lie algebra (which is also a Leibniz algebra) can also be described as the space of linear derivations on the associative algebra \( C^{\infty} (M) \) of smooth functions on the given manifold. Here, we are interested in finding Leibniz algebras as a canonical extension of the Lie algebra \( \text{Der} (A) \) of linear derivations on an arbitrary associative algebra \( A \) both over the same coefficient ring \( \mathbb{K} \). This leads us to consider a notion of Courant pair denoted simply by \((A,L)\). The deformation of algebraic and analytic structures are an important aspects if one studies their properties. They characterize the local behaviour in a small neighbourhood in the variety of a given type of objects.

A Courant pair \((A,L)\) consists of an associative algebra \( A \) and a Leibniz algebra \( L \) over the same coefficient field \( \mathbb{K} \), equipped with a Leibniz algebra homomorphism \( \mu : L \rightarrow \mathfrak{g} \), where \( \mathfrak{g} \) denotes the Lie algebra of \( \mathbb{K} \)-linear derivations on \( A \) under the commutator bracket. If we replace the Lie algebra in the definition by a Lie algebra then what we obtain is a Leibniz pair \((A,L)\) introduced by Flato et al. [8]. The notion of Leibniz pair was defined as a generalization of the Poisson algebras and a formal deformation theory is studied in ref. [8]. Later on it is found as a special case of a homotopy algebra introduced by Kajiura and Stashef [9]. They referred this as an open closed homotopy algebra (OCHA). A Lie algebroid or its algebraic counterpart, called a Lie-Rinehart algebra [10] is also a special type of Leibniz pair by considering associative algebras also to be a commutative algebra.

A Courant pair appears naturally when one consider a Lie algebroid [11] or more generally a Leibniz algebroid [12] (or Loday algebroid, Courant algebroid [13,14]) over a smooth base manifold. In all these cases the underline Lie algebra of the Courant algebras are considered to be the Lie algebra of vector fields or space of linear derivations of the associative algebra of functions on the manifold. More examples can be found if one allow Leibniz algebras in place of Lie algebra in the definition of a Leibniz pairs \((A,L)\). Here, we consider this more general case of Leibniz pair in the name of Courant pair which will form a category containing the category of Leibniz pairs as a full subcategory. The cohomology space is different if one consider a Leibniz pair as an object in the larger category of Courant pairs.

The paper is organized as follows: In section 2, we recall the Hochschild cohomology of an associative algebra with coefficient in a bimodule, a Leibniz algebra cohomology complex with coefficient in a representation and the notion of Courant algebras with examples. Section 3 contains definition and various natural examples of the notion of Courant pairs. We discuss about representations or modules over a Courant pair as a suitable semi-direct products in the category of associative and Leibniz algebras respectively with corresponding modules. In section 4, we present the construction of a deformation bicomplex for a Courant pair \((A,L)\) from Hochschild cohomology complex of the associative algebra \( A \) and Leibniz cohomology complex.
for the Leibniz algebra $L$. In section 5 we define one parameter formal deformation of a Courant pair, define the notion of equivalence of deformations, and study rigidity. In the last section we discuss about the obstruction cochains that arises in extending deformation of finite order with given infinitesimal. We mentioned examples to show that one can find many more deformations of a Leibniz pair when it is deformed as a Courant pair by using the new bicomplex cohomology.

One of the main results in any deformation theory is to prove that obstruction cochains are cocycles. In our context, this consists of three parts; one arising from deformations of the considered associative algebra, one from the deformation of the Leibniz algebra and the other from deformation of the Leibniz homomorphism of a Courant pair. In ref. [15], Gerstenhaber showed that the obstruction cochains arising from deformations of associative algebras are cocycles and in ref. [16] Balavoine showed the obstruction cochains arising from deformations of Leibniz algebras are cocycles. The other part is done by a direct computation and given in below Appendix.

Throughout we will consider vector spaces over a field $K$ of zero and all maps are $K$-linear unless otherwise it is specified.

**Preliminaries**

**Associative algebras and its cohomology**

**Definition 2.1:** Let $A$ be an associative algebra over $K$, a bimodule $M$ over $A$ or, an $A$-bimodule is a $K$-module equipped with two actions (left and right) of $A$.

$$A \times M \to M \text{ and } M \times A \to M.$$ such that $(am)a' = a(ma')$ for $a, a' \in A$ and $m \in M$.

The actions of $A$ and $K$ on $M$ are compatible, that is $(\lambda a)m = \lambda (am)$ for $\lambda \in K, a \in A$ and $m \in M$. When $A$ has the identity 1 we always assume that $1m = m1 = m$ for $m \in M$.

Given a bimodule $M$ over $A$, the Hochschild cochain complex of $A$ with coefficients in $M$ is defined as follows. Set $C^n(A, M) = \text{Hom}_K(A^n, M); n \geq 0$ where $A^n = A \otimes \ldots \otimes A (n$-copies). Let $\delta^n C^n(A, M) \to C^{n+1}(A, M)$ be the $K$-linear map given by:

$$\delta^n f(a_1, a_2, \ldots, a_n) = a_n f(a_1, a_2, \ldots, a_{n-1}) + \sum_{i=1}^n (-1)^{i} f(a_1, \ldots, a_{i-1}, a_i a_{i+1}, \ldots, a_n)$$

Then $\delta^n f = 0$ and the complex $(C(A, M), \delta)$ is called the Hochschild complex of $A$ with coefficients in the $A$-bimodule $M$. When $M = A$, the actions are given by algebra operation in $A$ we denote the complex $C(A, A)$ by $C(A)$. The graded space $C(A)$ is a differential graded Lie algebra (or DGLA) in short [15].

**Definition 2.2:** A graded Lie algebra $\mathfrak{L}$ is a graded module $\mathfrak{L} = \{L_i\}_{i \geq 0}$ together with a linear map of degree zero, $[-,-] : \mathfrak{L} \otimes \mathfrak{L} \to \mathfrak{L}$, $x \otimes y \mapsto [x, y]$ satisfying:

(i) $[x, y] = -(−1)^{|x||y|}[y, x] \text{ (graded skewsymmetry)}$

(ii) $(-1)^{|x||y|} [x, [y, z]] + (-1)^{|y||z|} [y, [x, z]] + (-1)^{|z||x|} [z, [x, y]] = 0 \text{ (graded Jacobi identity)}$

for $x, y, z \in \mathfrak{L}$, where $|x|$ denotes the degree of $x$.

A differential graded Lie algebra is a graded Lie algebra equipped with a differential $d$ satisfying:

$$d[x, y] = [dx, y] + (-1)^{|x|}[x, dy].$$

**Remark 2.3:** The shifted Hochschild complex $C^*(A, A) = C^{*(1)}(A, A)$ is a DGLA where the graded Lie bracket is also called the Gerstenhaber bracket.

Let $\phi$ be a Hochschild $p$-cochain and $\theta$ be a Hochschild $q$-cochain. The Gerstenhaber bracket of $\phi$ and is the $(p+q)$-cochain defined by:

$$[\phi, \theta] = \phi \theta - (-1)^{p(q+1)} \theta \phi.$$

Where,

$$\phi \theta(a_1, \ldots, a_{p+q+1}) = \sum_{0 \leq i \leq p} (-1)^i \phi(a_1, \ldots, a_i, \theta(a_{i+1}, \ldots, a_{p+q}), \ldots, a_{p+q+1}).$$

Also, note that if $a_i$ is the associative multiplication, then $\delta_i$ can be written in terms of the Gerstenhaber bracket and the multiplication $a_i$:

$$\delta_i \phi = (-1)^i [a_i, \phi].$$

**Leibniz algebra and its cohomology**

Now, we recall the definition of a Leibniz algebra and describe its cohomology.

**Definition 2.4:** A Leibniz algebra (left Leibniz algebra) is a $K$-module $L$, equipped with a bracket operation, which is $K$-bilinear and satisfies the Leibniz identity,

$$[x, [y, z]] = [[x, y], z] + [y, [x, z]] \text{ for } x, y, z \in L.$$

In the presence of antisymmetry of the bracket operation, the Leibniz identity is equivalent to the Jacobi identity, hence any Lie algebra is a Leibniz algebra.

**Remark 2.5:** For a given Leibniz algebra $L$ as defined above, the left adjoint operation $[x, -]$ is a derivation on $L$ for any $x \in L$. Analogously, Leibniz algebra (right Leibniz algebra) can be defined by requiring that the right adjoint map $[-, x]$ is a derivation for any $x \in L$. In that case, the Leibniz identity appeared in the above definition would be of the form:

$$[x, [y, z]] = [[x, y], z] - [y, [x, z]] \text{ for } x, y, z \in L.$$

Sometime, in the literature right Leibniz algebra has been considered. All our Leibniz algebras in the present discussion will be left Leibniz algebras unless otherwise stated.

**Example 2.6:** Let $(g[\cdot, \cdot])$ be a Lie algebra and $V$ be a $g$-module with the action $(x \cdot v) = -xv$. Take $L = g \oplus V$ with the bracket given by:

$$[[x, y], w]] = [[x, y], w] \text{ for } x, y, w \in L.$$

Then $(L, [-, -])$ is a Leibniz algebra. This bracket is called hemisemidirect product in ref. [7].

This shows that one can associate a Leibniz algebra $L$ to a smooth manifold $M$. If $g$ is the Lie algebra of Vector fields $\chi(M)$ over a smooth manifold, then $C^{\infty}(M)$ is a $(\chi(M))$-module with the left action $\chi(M) \times C^{\infty}(M) \to C^{\infty}(M); (X, f) \mapsto Xf$. It follows that $L = \chi(M) \otimes C^{\infty}(M)$ is a Leibniz algebra with the bracket given by:

$$[[X, f], (Y, g)] = [X, Y] (Xf).$$

There are various other sources to generate more examples of Leibniz algebras which may not be a Lie algebra.

**Example 2.7:** Let $A$ be an associative $K$-algebra equipped with a $K$-linear map $D : A \to A$, such that $D^2 = D$. Define a bilinear map $[-, -]: A \otimes A \to A$ by:

$$[x, y] = (Dx)y - y(Dx) \text{ for all } x, y \in A.$$

Then $(A, [-, -])$ is a left Leibniz algebra. In general, $A$ with the above bracket is not a Lie algebra unless $D = id$. 
Example 2.8: Let $(L, d)$ be a differential Lie algebra with the Lie bracket $[-,-]$. Then $L$ is a Leibniz algebra with the bracket operation $[x, y] := [dx, y]$. The new bracket on $L$ is called the derived bracket [17].

One can find more examples appeared in refs. [4-6,18,19].

Definition 2.9: Suppose $L$ and $M$ are Leibniz algebras, a linear map $\phi: L \to L'$ is called a homomorphism of Leibniz algebras if it preserves the Leibniz bracket, i.e.

$$\phi([x, y]) = [\phi(x), \phi(y)], \text{ for all } x, y \in L.$$

Leibniz algebras with Leibniz algebra homomorphisms form a category of Leibniz algebras, which contains the category of Lie algebras as a full subcategory.

Let $L$ be a Leibniz algebra and $M$ be a representation of $L$. By definition [6,19], $M$ is a $K$-module equipped with two actions (left and right) of $L$,

$$[\cdot, \cdot]: L \times M \to M \quad \text{and} \quad \cdot \cdot \cdot : M \times L \to M,$$

such that for $m \in M$ and $x, y \in L$ following hold true,

$$[m, [x, y]] = [[m, x], y] + [m, [x, y]],$$

$$[x, my] = [xm, y] + [x, ym],$$

$$x(y, m) = (y, x)m = [x, y]m + [y, x]m.$$

Define $\text{CL}(L; M) := \text{Hom}_K(L^2, M)$, $n \geq 0$. Let $\text{CL}(L; M) \to \text{CL}(L; M)$ be a $K$-homomorphism defined by:

$$(\delta \phi)(X, X_1, \ldots, X_n) = \sum_{i=1}^n (-1)^{i-1} \phi([X_1, \ldots, X_i, X_{i+1}, \ldots, X_n]) + (-1)^n \phi([X, X_1, \ldots, X_n]),$$

$$= \sum_{i=1}^n (-1)^{i-1} \phi([X, X_1, \ldots, X_i, X_{i+1}, \ldots, X_n]).$$

Then $(\text{CL}(L; M), \delta)$ is a cochain complex, whose cohomology is denoted by $H^*(L; M)$, is called the cohomology of the Leibniz algebra $L$ with coefficients in the representation $M$ [6,19]. In particular, $L$ is a representation of itself with the obvious actions given by the Leibniz algebra bracket of $L$.

### Courant algebras over a Lie algebra

Now, we recall the definition of Courant algebras from ref. [1]. Let $g$ be a Lie algebra over $K$.

**Definition 2.10:** A Courant algebra over a Lie algebra $g$ is a Leibniz algebra $L$ equipped with a homomorphism of Leibniz algebras $\pi: L \to g$. We will simply denote it as $\pi: L \to g$ a Courant algebra.

**Example 2.11:** A Courant algebroid over a smooth manifold $M$ gives an example of a Courant algebra over the Leibniz algebra of vector fields $\mathfrak{X}(M)$ by taking $\mathfrak{X}(M)$ as the Leibniz algebra structure on the space of sections of the underlying vector bundle of the Courant algebroid. From ref. [14] it follows that any Courant algebra is actually an example of a 2-term $L$-algebra [20,21].

**Definition 2.12:** An exact Courant algebra over a Lie algebra $g$ is a Courant algebra $\pi: L \to g$ for which $\pi$ is a surjective linear map and $\mathfrak{h} := \ker(\pi)$ is abelian, i.e. $[h_1, h_2] = 0$ for all $h_1, h_2 \in \mathfrak{h}$.

For an exact Courant algebra $\pi: L \to g$, there are two canonical actions of $g$ on $\mathfrak{h}$: $[g, h] := [a, h]$ and $[h, g] := [h, a]$ for any $a$ such that $\pi(a) = g$. Thus the $K$-module $\mathfrak{h}$ equipped with these two actions denoted by the same bracket notation $[-,-]$, is a representation of $g$ (viewed as a Leibniz algebra).

The next example will give a natural exact Courant algebra associated with any representation of the Lie algebra $g$.

**Example 2.13:** As in Example 2.6, $g$ be a Lie algebra acting on the vector space $V$. Then $L=\mathfrak{g} \times V$ becomes a Courant algebra over $\mathfrak{g}$ with the Leibniz algebra homomorphism given by projection on $g$ and the Leibniz bracket on $L$ given by:

$$[(g_1, h_1), (g_2, h_2)] = ((g_1, g_2), h_1h_2).$$

Where $g.h$ denotes the action of the Lie algebra $g$ on $V$.

In ref. [2] it is shown that exact Courant algebras over a Lie algebra $g$ can be characterised via Leibniz 2-cocycles, and the automorphism group of a given exact Courant algebra is in a one-to-one correspondence with first Leibniz cohomology space of $g$. Exact Courant algebras also appeared in the general study of Leibniz algebra extension and a discussion of some unified product for Leibniz algebras is in refs. [22,23].

**Example 2.14:** If we consider a Leibniz representation $\pi$ of the Lie algebra $g$, then $L=\mathfrak{g}$ becomes a Courant algebra over $\mathfrak{g}$ via the bracket:

$$[(g_1, h_1), (g_2, h_2)] = ([g_1, g_2], [g_1, h_2] + [h_1, g_2]),$$

where the actions (left and right) of $g$ on $\mathfrak{h}$ are denoted by the same bracket $[-,-]$.

### Courant Pairs

In this section we introduce the notion of a Courant pair and discuss about various natural examples. We define representation or modules of a Courant pair as a suitable semi-direct product in the category of associative and Leibniz algebras respectively with corresponding modules.

Let $A$ be an associative algebra over $K$ and by $g$, we denote the Lie algebra of derivations $\text{Der}_A(A)$ of linear derivations of $A$ with commutator bracket $[-,-]$. Now we define a Courant pair as a Courant algebra over the Lie algebra $g$ which is canonically associated to a given associative algebra $A$.

**Definition 3.1:** A Courant pair $(A, L)$ consists of an associative algebra $A$ and a Lie algebra $L$ over the same coefficient ring $K$, and equipped with a Leibniz algebra homomorphism $\mu: L \to g$.

**Remark 3.2:** It follows from the definition that a Courant pair $(A, L)$ can be expressed as a triplet of the involved algebra operations and homomorphism $(\alpha, \mu, \lambda)$. Here, $\alpha: A \times A \to A$, denotes the associative multiplication map on $A$, $\lambda: L \times L \to L$, denotes the Leibniz bracket in $L$ and the homomorphism $\mu$ defines an action $\mu: L \times A \to A$ given by $\mu(\lambda(a), b) = \mu(\lambda(a))$ for all $a \in L$ and $b \in A$.

Every Leibniz pair defined in ref. [8] is an example of a Courant pair. In fact, if $(A, L)$ is a Leibniz pair then by definition, $A$ is an associative algebra and $L$ is a Lie algebra over some common coefficient ring $K$, connected by a Lie algebra morphism $\mu: L \to g$. And since the category of Lie algebras is a subcategory of the Leibniz algebra category, it follows that a Leibniz pair is also a Courant pair. In particular,

1. A Poisson algebra $A$ gives a Courant pair $(A, A)$ with the Lie algebra homomorphism $\mu = ad$.

2. Any Lie algebroid $(E, [-,-], \rho)$ gives a Courant pair $(C^*(E), T)$ where $C^*(E)$ is the graded associative algebra of functions on $E$.
with the Leibniz algebra homomorphism $\mu = \rho$.

3. Any Lie-Rinehart algebra $(A, L)$ is also a Courant pair satisfying the additional conditions that $A$ as a commutative algebra, $L$ as an $A$-module and $\mu : L \to g$ as an $A$-module morphism such that $[x, fy] = f[x, y] + \mu(x)(fy)$ for $x, y \in L$ and $f \in A$.

**Example 3.3:** Let $A$ be an associative commutative algebra and a module over the Lie algebra $g = (\mathrm{Der}(A), [-,-])$, where $g$ acts on $A$ via derivations. As in Example 2.4, if we consider the Leibniz algebra $L = \mathrm{Der}(A) \oplus A$, then $(A, \mathrm{Der}(A) \oplus A)$ is a Courant pair, where the Leibniz algebra morphism $\mu$ is given by the projection map from $\mathrm{Der}(A) \oplus A$ onto $\mathrm{Der}(A)$.

**Remark 3.4:** In particular, for $A$ to be the space of smooth functions on a smooth manifold this type of examples of Courant pair appears as twisted Dirac structure of order zero in ref. [24].

In the sequel, one can find Courant pairs associated to an algebra by considering modules and flat connections on the module of the algebra.

Let $A$ be an associative algebra and $V$ be an unitary $A$-module. A derivation law, or Koszul connection on $V$ is an $A$-linear mapping $V : \mathrm{Der}(A) \to \mathrm{Hom}(V, V)$ (the image of $X = \mathrm{Der}(A)$ is denoted by $V_x$) such that $V(fX) = fV_x + X(f)v$ for $X \in \mathrm{Der}(A), f \in A$, and $v \in V$. Further, the connection $V$ is called flat connection if $V_{[X, Y]} = [V_x, V_y]$. Now, $(\mathrm{Der}(A), [-,-])$ is a Lie algebra. If $V$ is a flat connection on $V$, then $V$ is a $\mathrm{Der}(A)$-module. Therefore, a semidirect product of $\mathrm{Der}(A)$ and $V$ defines a Leibniz bracket on the $A$-module $\mathrm{Der}(A) \oplus V$ as:

$[(x, v), (y, w)] = ([X, Y], [V_x, V_y])$

Where, $v, w \in V$. Therefore, we have a Courant pair $(A, \mathrm{Der}(A) \oplus V)$ with Leibniz algebra morphism $\mu$ given by the projection map onto $\mathrm{Der}(A)$.

Now, for a Lie algebroid $(E, [-,-])$ over $M$ and a flat $E$-connection on a vector bundle $F \to M$, there is an associated Courant pair $(A, L)$ where $A$ is a algebra of smooth functions on $M$ and $L$ is the semidirect product Leibniz algebra obtained from the space of sections of the Lie algebroid and the vector bundle respectively.

**Example 3.5:** Let $(E, [-,-], \rho)$ be a Lie algebroid over a manifold $M$. An $E$-connection on a vector bundle $F \to M$ is an $A$-linear map:

$V : \Gamma E \to \Gamma \mathfrak{h}(\Gamma F, TF)$

satisfying following properties:

$V_{\rho_x(a)}(v) = fV_x(a), V_x(fv) = fV_x(a) + \rho(X)(v)f, a$,

for $x \in \Gamma E, f \in \mathcal{C}(M)$, and $a \in \mathcal{C}$. Here, $\Gamma E$ is the Lie algebra of $\mathcal{C}$-sections of $E$. An $E$-connection is called flat if $\nabla_{[X, Y]} = [\nabla_x, \nabla_y]$. A flat $E$-connection on a vector bundle $F \to M$ is also called a representation of $E$ on $F \to M$ [11].

Now, $\Gamma E$ is a Lie algebra and $\Gamma F$ is a $\Gamma E$-module (it follows from flatness of $\nabla$). Therefore, by taking semidirect product of $\Gamma E$ and $\Gamma F$, we have a Leibniz algebra bracket on $\Gamma E \otimes \Gamma F$ given by:

$[(X, a), (Y, b)] = [(X, Y), [V_x, V_y]]$

for $X, Y \in \Gamma E$ and $a, b \in \Gamma F$. Consider $A = C^*(M)$, and $L = \Gamma E \otimes \Gamma F$, then $(A, L)$ is a Courant pair with the Leibniz algebra morphism $\mu : \Gamma E \otimes \Gamma F \to \Gamma E \otimes \Gamma F = \mathrm{Der}(A)$ where $\mu = \rho \circ \pi_1$, and $\pi_1$ is the projection map onto $\Gamma E$.

**Example 3.6:** Let $R$ be a commutative unital ring and $A$ be a commutative unital $R$-algebra. Recall from [12], a Leibniz pseudoalgebra $(\varepsilon, [-,-], \rho)$ over $(R, A)$ consists of an $A$-module $\varepsilon$, an $A$-module homomorphism $\rho : \varepsilon \to \mathrm{Der}(A)$ and $A$ a Leibniz algebra structure $[-,-]$, on $\varepsilon$ such that:

$[X, Y] = f(X, Y) + \rho(x)(Y),$ for all $f \in A$ and $X, Y \in \varepsilon$. Every Leibniz pseudoalgebra $(\varepsilon, a, [-,-])$ over $(R, A)$ gives a Courant pair $(\varepsilon, a)$.

In particular, any Leibniz algebra $E$ over a smooth manifold $M$ is a Leibniz pseudoalgebra over $(R, C^*(M))$. So, it gives a Courant pair $(C^*(M), \Gamma(E))$.

**Example 3.7:** Suppose $A$ is a associative and commutative algebra. Let $\Omega^1_\varepsilon$ be the $A$-module of Kahler differentials [25], with the universal derivation:

$d_a : A \to \Omega^1_\varepsilon.$

Consider the $A$-module $\mathrm{Der}(A) \otimes \Omega^1_\varepsilon$ equipped with the Leibniz bracket given by:

$[(X, a), (Y, b)] = [(X, Y), L_{X_{\varepsilon}}, d_a].$

Then $(A, \mathrm{Der}(A) \otimes \Omega^1_\varepsilon)$ is a Courant pair. This shows that a Courant pair is also appeared in the context of Courant-Dorfman algebras introduced in ref. [26].

**Remark 3.8:** A Courant-Dorfman algebra [26] has an associated Leibniz pseudoalgebra (or Leibniz-Rinehart algebra) and an associated Courant pair structure.

**Example 3.9:** Any Courant algebroid $(C, [-,-], \rho)$ (algebraic counterpart defined in ref. [13]) is a Leibniz pseudoalgebra $(C, [-,-], \rho)$. So, any Courant algebroid has a underlying Courant pair.

**Modules of courant pairs**

Suppose $(A, L)$ is a Courant pair. We define modules of $(A, L)$ as a suitable Courant algebra by considering semi-direct products of associative and Leibniz algebras with respective modules of these algebras. Suppose that $M$ is an $(A, A)$-bimodule and $P$ an $A$-module. We denote by $A + M$ and $L + P$, respectively, the associative and Leibniz semidirect products. Now we define modules over a Courant pair, using the following general principle; if $(A, L)$ is a Courant algebra, then an $(A, L)$-module is a pair $(M, P)$ such that $(A + M, L + P)$ is also a Courant pair and contains $(A, L)$ as a subobject and $(M, P)$ as an abelian ideal in an appropriate sense.

**Definition 3.10:** A module over a Courant pair $(A, L)$ means a pair $(M, P)$, where $P$ is a Leibniz algebra module over $L$, $M$ is an $(A, A)$-bimodule, and there is a Leibniz algebra homomorphism $\tilde{\mu} : (L + P) \to \mathrm{Der}_L(A + M)$ extending the Leibniz algebra morphism $\mu : L \to \mathrm{Der}_L(A)$ in the following sense:

1. $\tilde{\mu}(0, a)(0) = \mu(a)$ for any $a \in L, a \in A$.
2. $\tilde{\mu}(0, a)(0, m) = \mu(a, m)$ for any $m \in L, a \in A, a \in P, m \in M$.
3. $\tilde{\mu}(0, m)(0, m) = 0$ for any $a \in P, m \in M$.

**Remark 3.11:** Every Courant pair $(A, L)$ is a module over itself. This fact will be useful in the later section while considering deformations. We may also canonically define morphisms of Courant pairs and hence morphisms of modules of a given Courant pair $(A, L)$.

**Note 3.12:** It is important to notice here that for each $a \in P$ the map $A \to M$ defined by sending $a$ to $\tilde{\mu}(0, a)(0, 0)$ is a derivation of $A$ into $M$. 

ISSN: 1736-4237

Volume 11 • Issue 3 • 1000281
This yields a map $\phi: P \to \text{Der}(A,M)$, which we will use in the double complex defined later.

Deformation Complex of a Courant pair

In the present section, we introduce the deformation complex of a Courant pair. We shall observe subsequently that the second and the third cohomologies associated to this cohomology complex encode all the information about deformations. Suppose $(M,P)$ is a module of the Courant pair $(A,L)$. So $M$ is an $A$-bimodule and $P$ is a Leibniz-L-module. We need to consider the Hochschild complex $C(A,M)$ and Leibniz algebra complex $C(L,P)$ in the sequel. Here we will denote the tensor modules $\otimes$ simply by $\otimes$.

Let $C(A,M) = \text{Hom}(A,M)$, the $p$-th Hochschild cochain group of $A$ with coefficients in $M$. Note that $C(A,M) = M$. Now $C^*(A,M)$ is an $A$-module (symmetric Leibniz algebra module) by the actions given as:

$$[x, f](a_1, \ldots, a_n) = [x, f(a_1, a_2, \ldots, a_n)] - \sum_{i=1}^{n-1} f(a_1, \ldots, a_i, x, a_{i+1}, \ldots, a_n)$$

and $[f, x] = [f, x]_f$ for $f \in C^p$ and $x \in L$. Here, $\{m, x\} = -[m, x] = \bar{\mu}(x)(m)$ for $a \in A$, $m \in M$, and $x \in L$. One can check that,

$$[(xy)f]_f = [x, [y, f]] - [y, [x, f]],$$

for $x, y \in L$ and $f \in C^p$. It follows that the Lie algebra $\text{Der}(A,M)$ of linear derivation from $A$ to $M$ is a Leibniz algebra submodule of $C(A,M)$ and the mapping $\phi: P \to \text{Der}(A,M)$ defined in the previous section in $L$ as a module over this Leibniz pair. Also,

$$\phi(xp) = [x, \phi(p)] (\text{using the Leibniz algebra structure on the semi-direct product space } L \cdot P).$$

Recall the Hochschild coboundary $\delta C^p \to C^{p+1}$ is given by:

$$(\delta C^p)(a_1, \ldots, a_{p+1}) = a f(a_1, \ldots, a_{p+1}) + \sum_{k=1}^{p+1} (-1)^k f(a_1, \ldots, a_k, a_{k+1}, \ldots, a_{p+1}) + (-1)^p f(a_1, a_2, \ldots, a_{p+1}).$$

Now it follows that $\delta_0$ is a Leibniz algebra module homomorphism by using the definitions of the map $\delta_0$ and $L$-module action on $C^0$.

Proposition 4.1: Let $(M,P)$ be a module over a Courant pair $(A,L)$. Then $\delta C^2 \to C^3$ is a homomorphism of Leibniz algebra modules over $L$, i.e., $\delta([x, f]) = [x, \delta f]$ for $x \in L$ and $f \in C^2$.

Let $(M,P)$ be a module of the Courant pair $(A,L)$. We now define a double complex for $(A,L)$ with coefficients in the module $(M,P)$ as follows:

$$C^p_q = \text{Hom}(L^p \otimes C^q, C^*(A,M))$$

for all $(p,q) \in \mathbb{Z} \times \mathbb{Z}$ with $p, q \geq 0$, where $C^p_q = \text{Hom}(L^p \otimes C^q, C^*(A,M))$. For $p \geq 0$, we consider the vertical coboundary map $C^0_q \to C^{1,q}$ is the Hochschild coboundary map $\delta_q$ for $p = 0$ and for all $q$, action of $P$ on $A$ derivations induces the map $\delta C^p_q \to C^{p+1}_q$. For $p = 0$, vertical maps are Hochschild coboundaries, and $\text{Der}(A,M)$ the kernel of $\delta C^0_q \to C^{1,q}$. Therefore, the composition of two vertical maps is zero for all $p$ and $q$.

In the horizontal direction, we have for all $p$ and $q$ the Leibniz algebra coboundary $\delta C^p_q \to C^{p+1}_q$. Since all the vertical coboundaries are Leibniz module homomorphisms, it follows that they commute with all the horizontal ones. Therefore, we can define a total cochain complex as follows: For $p \geq 0$.

$$C^p = \bigoplus_{q \geq 0} C^p_q$$

and $\delta_0 : C^p \to C^{p+1}$. The resulting cohomology of the total complex we define to be the cohomology of the given Courant pair $(A,L)$ with coefficients in the module $(M,P)$, and we denoted this cohomology as $H(L \cdot P)$.

In particular for $(M, P) = (L, A)$, with the obvious actions the cohomology is denoted by $HL(A;L)$. We will recall this cohomology in the next section for the deformation of Courant pairs.

Remark 4.2: The cohomology spaces are different if one consider a Leibniz pair as an object in the larger category of Courant pairs. Recall from ref. [8], $H^*_{\text{L}}(A;L)$ is the cohomology space for Leibniz pair $(A,L)$ with coefficients in the module $(M,P)$. Consider the Leibniz pair $(\text{Der}(\mathbb{R}^{d,0}), \mathbb{R}^{\mathbb{R}^{d,0}})$ as a module over this Leibniz pair. It follows that $H^*_{\text{L}}(\mathbb{R}^{d,0}, \mathbb{R}^{\mathbb{R}^{d,0}})$.

On the other hand if we take $(\text{Der}(\mathbb{R}^{d,0}), \mathbb{R}^{\mathbb{R}^{d,0}})$ as a module over it, the $H^*_{\text{L}}(\mathbb{R}^{d,0}, \mathbb{R}^{\mathbb{R}^{d,0}})$ are different as there are new generators for the dual Leibniz algebra structure over the Leibniz cohomology space [27,28].

This shows that, while considering a Leibniz pair $(\text{Der}(\mathbb{R}^{d,0}))$ as an object in the category of Courant pairs, we have a somewhat different cohomology space.

Deformation of Courant Pairs

In this section, we study formal deformation of Courant pairs. All the basic notions of deformation theory of algebraic structures are originally due to M. Gerstenhaber [15,29-31]. Here we briefly describe the analogous concepts related to deformation of a Courant pair. This can be viewed as a generalization of the deformation of Leibniz pairs [8] to a larger category by allowing more deformations.

Let $(L,A)$ be a Courant pair, then using remark (3.2), it can be viewed as a triple $(\alpha, \mu, \lambda)$. Recall that a formal 1-parameter family of deformations of an associative algebra $A$ is an associative product $a_{\lambda}$ on the $A[[t]]$-module $A[t] = \mathbb{A}_{\otimes} A[[t]]$, where $a_\lambda = \sum a_{\lambda}^t t^t$, $a_{\lambda}^t \in C^p(A)$ with $a_{\lambda}^t$ being the algebra product on $A$. Analogously, a formal 1-parameter family of deformations of a Leibniz algebra $L$ is a Leibniz bracket $\lambda$ on the $A[[t]]$-module $L[[t]] = \mathbb{A}_{\otimes} L[[t]]$, where $\lambda_{\lambda} = \sum a_{\lambda}^t t^t$, $a_{\lambda}^t \in C^2(L)$ with $a_{\lambda}^t$ denotes the original Leibniz bracket on $L$.

Definition 5.1: A deformation of a Courant pair $(L,A)$ whose structure maps are $(\alpha, \mu, \lambda)$ is defined as a tuple of the form $(\alpha, \mu, \lambda, \psi)$, where $\alpha$, is a deformation of an algebra, i.e., an associative $A[[t]]$-algebra product $A[t] \to A[t]$. Consider the deformation $a_{\lambda}$ of $A$ to $a_{\lambda}$ in $A[t]$ such that $a_{\lambda} = \sum a_{\lambda}^t t^t$, where $a_{\lambda}^t = a_t$, $\lambda_{\lambda} = \sum a_{\lambda}^t t^t$, $a_{\lambda}^t \in C^p(A)$ with $\mu_t$, $\mu_t = \mu$. Also following compatibility conditions among $\alpha_t$ and $\lambda_t$ are satisfied:

\begin{align*}
\mu(x_a(a))(b) &= a_t(\mu(x_a(a)),b) + a_t(\mu(x_a(b)),a) \\
\lambda_t(x_a(a),b) &= \mu_t(x_a(a),b) - \mu_t(x_a(b),a).
\end{align*}

By above definition we have also the following equations, using the fact that $\alpha_t$ and $\lambda_t$ are deformations of the associative multiplication $a$ on $A$ and the Leibniz bracket $\lambda$ on $L$, respectively:

\begin{align*}
\alpha_t(a_t(b,c)) &= a_t(a_t(b,c)),
\end{align*}

whenever $a_t, b, c \in A$ and $a, b, c \in L$. We will denote this cohomology as $H(L \cdot P).$
\[ \lambda(x, \lambda(y, z)) = \lambda(\lambda(x, y), z) + \lambda(y, \lambda(x, z)). \]  

Now expanding both sides of the above equations and collecting coefficients of \( t^n \), we get the following equations for \( a, b, c \in L \):

\[ \sum_{r+s=n} \mu_r(\lambda(x, \alpha(a, b))) = \sum_{r+s=n} \alpha_r(\mu_r(x, b)) + \alpha_r(\mu_r(x, a), b); \]  
\[ \sum_{r+s=n} \mu_r(\lambda(x, y, a)) = \sum_{r+s=n} \mu_r(x, \mu_r(y, a)) - \mu_r(y, \mu_r(x, a)); \]  
\[ \sum_{r+s=n} \lambda_r(x, \lambda_r(y, z)) = \sum_{r+s=n} \lambda_r(\lambda_r(x, y), z) + \lambda_r(y, \lambda_r(x, z)); \]  
\[ \sum_{r+s=n} \alpha_r(a, \alpha_r(b, c)) = \sum_{r+s=n} \alpha_r(a, \alpha_r(b, c)). \]

**Remark 5.2:** For \( n=0 \), eqns. (1) and (2) imply that \( \mu \) is a Leibniz algebra morphism from \( L \) into \( \text{Der}(A) \), and (4), (3) implies the usual Leibniz identity for \( \lambda \) and the associativity of the multiplication \( \alpha \). Now, the map \( \delta : L \rightarrow \text{Hom}(L, \text{C}(A, A)) \rightarrow \text{Hom}(L^{\otimes n}, \text{C}(A, A)) \) is defined as:

\[ \delta f (x_1, \ldots, x_n) = (-1)^{\eta_1} \sum_{i=1}^{n} (-1)^{n_1} f(x_1, \ldots, \hat{x}_i, \ldots, x_n). \]

So, for \( n \geq 1 \), eqns. (8) and (7) imply that \( \delta(\alpha) = 0, \delta(\lambda) = 0 \) and eqns. (5) and (6) imply that \( \delta(\lambda) + \delta(\alpha) = 0 \) and \( \delta(\lambda) - \delta(\mu) = 0 \). Thus, for \( n=1 \), eqns. (5)-(8) give that \( \delta(\alpha, \lambda) = 0 \). So, \( (\alpha, \lambda) \) is a 2-cocycle in the double complex described in the previous section.

**Definition 5.3:** The 2-cocycle \( (\alpha, \lambda, \mu) \) is called the infinitesimal of the deformation \( (\alpha, \lambda, \mu) \). More generally, if \( (\alpha, \lambda, \mu) = (0, 0, 0) \), and \( (\alpha, \lambda, \mu) \) is a non zero cochain in \( C_{\alpha, \lambda, \mu}^{2} \), then \( (\alpha, \lambda, \mu) \) is called the n-infinitesimal of the deformation \( (\alpha, \lambda, \mu) \).

**Proposition 5.4:** The infinitesimal \( (\alpha, \lambda, \mu) \) of the deformation \( (\alpha, \lambda, \mu) \) is a 2-cocycle in \( C_{\alpha, \lambda, \mu}^{2} \). More generally, the n-infinitesimal is a 2-cocycle.

**Definition 5.5:** We say that \( (\alpha, \lambda, \mu) \) is equivalent to \( (\tilde{\alpha}, \tilde{\lambda}, \tilde{\mu}) \), where \( \tilde{\alpha} = \sum_i f_i \tilde{\alpha} \) and \( \tilde{\alpha} = \alpha \), etc., if there exists \( K[[t]] \)-linear maps \( \Phi = id_A + \sum f_i : A[[t]] \rightarrow A[[t]] \) (with each \( f_i \) a linear map \( A \rightarrow A \) extended to be \( K[[t]] \)-linear) and \( \Psi = id_A + \sum \phi_i : L[[t]] \rightarrow L[[t]] \) such that:

\[ \tilde{\alpha}(a, b) = \Phi \circ \alpha(a, b), \]  
\[ \tilde{\mu}(\Psi(x, \alpha(a, b)), \Phi) \]  
\[ \tilde{\lambda}(x, y, z) = \Psi(\lambda(x, y, z)). \]

**Definition 5.6:** Any deformation of Courant pair equivalent to the deformation \( (\alpha, \lambda, \mu) \) is said to be a trivial deformation.

**Theorem 5.7:** The cohomology class of the infinitesimal of the deformation \( (\alpha, \lambda, \mu) \) of Courant pair is determined by the equivalence class of \( (\alpha, \lambda, \mu) \).

**Proof:** Let \( (\phi, \psi) : (\alpha, \lambda, \mu) \rightarrow (\tilde{\alpha}, \tilde{\lambda}, \tilde{\mu}) \) be an equivalence of these two deformations. Then expanding and comparing coefficients of t in the eqns. (9)-(11), we get

\[ \tilde{\lambda} - \lambda = \delta(\psi), \]  
\[ \tilde{\mu} - \mu = \delta(\psi), \]  
\[ \delta(\phi, \psi) = (\alpha, \lambda, \mu) - (\tilde{\alpha}, \tilde{\lambda}, \tilde{\mu}). \]

**Theorem 5.8:** A Courant pair is said to be rigid if every deformation of the Courant pair is trivial.

**Theorem 5.9:** A non trivial deformation of a Courant pair is equivalent to a deformation whose n-infinitesimal is not a coboundary for some \( n \geq 1 \).

**Proof:** Let \( (\alpha, \lambda, \mu) \) be a deformation of a Courant pair \( (\alpha, \lambda, \mu) \) with n-infinitesimal \( (\alpha, \lambda, \mu) \), for some \( n \geq 1 \). Assume that there exists a 1-cocycle \( (\phi, \psi) \) in \( C_{\alpha, \lambda, \mu}^{1} \) whose coboundary is the n-infinitesimal, i.e.,

\[ \delta(\phi, \psi) = (\alpha, \lambda, \mu). \]

This gives:

\[ \phi = id_A + \delta(\phi), \]  
\[ \psi = id_A + \delta(\psi). \]

(12)

Take,

\[ \phi = id_A + \delta(\phi), \]  
\[ \psi = id_A + \delta(\psi). \]

We define a deformation \( (\tilde{\alpha}, \tilde{\lambda}, \tilde{\mu}) \) of the Courant pair \( (\alpha, \lambda, \mu) \), where:

\[ \tilde{\alpha} = \Phi \circ \alpha(a, b), \]  
\[ \tilde{\mu}(\Psi(x, \alpha(a, b)), \Phi) = \Phi \circ \mu(a, b), \]  
\[ \tilde{\lambda}(\Psi(x, y, z)) = \lambda(\Psi(x, y, z)). \]

Taking above eqns. (12)-(15), we have:

\[ \tilde{\alpha} = \alpha, \]  
\[ \tilde{\mu} = \mu, \]  
\[ \tilde{\lambda} = \lambda. \]

(15)

And,

\[ \tilde{\alpha} = \alpha, \]  
\[ \tilde{\mu} = \mu, \]  
\[ \tilde{\lambda} = \lambda. \]

(16)

So, the given deformation \( (\alpha, \lambda, \mu) \) is equivalent to a deformation \( (\tilde{\alpha}, \tilde{\lambda}, \tilde{\mu}) \) for which \( (\tilde{\alpha}, \tilde{\lambda}, \tilde{\mu}) = 0 \), for \( 1 \leq i \leq n \). Hence, we can repeat the argument to kill off any infinitesimal that is a coboundary. So the process must stop if the deformation is non trivial.

**Corollary 5.10:** If \( H^{1}(A, L); A, L = 0 \), then the Courant pair \( (\alpha, \lambda, \mu) \) is rigid.

**Obstruction Cocycles**

In this section, we discuss about the problem of realising a 2-cocycle \( (\alpha, \lambda, \mu) \) in \( C_{\alpha, \lambda, \mu}^{2} \) as the infinitesimal of a deformation of the Courant pair. To this end first we define an obstruction cochain and then proceed by detecting any obstructions to extend a given deformation modulo \( t^n \) to a deformation modulo \( t^n+1 \), \( n \geq 1 \). Let \( N \) be a positive integer.

**Definition 6.1:** A deformation of Courant pair of order \( N \) is a \( (\alpha, \lambda, \mu) \) such that \( \alpha = \sum_{i=0}^{N} \alpha^{i}, \lambda = \sum_{i=0}^{N} \lambda^{i} \) and \( \mu = \sum_{i=0}^{N} \mu^{i} \) are deformations modulo \( t^{i+1} \) of \( A \) and \( L \), respectively, that is, \( \alpha \) and \( \lambda \) satisfy (7), respectively for \( 0 \leq i \leq N \), and \( \mu = \sum_{i=0}^{N} \mu^{i} \) satisfies eqns. (5) and (6).

If there exists a 2-cocycle \( (\alpha, \lambda, \mu) \) such that \( (\alpha, \lambda, \mu) \) is a deformation of \( (\alpha, \lambda, \mu) \) is a deformation of Courant pair of order \( (N+1) \), then we say that \( (\alpha, \lambda, \mu) \) extends to a deformation of Courant pair of order \( (N+1) \).

**Definition 6.2:** Let \( (\alpha, \lambda, \mu) \) be a deformation of Courant pair of order \( N \). Consider the cochains \( (\phi, \psi, \theta, \Theta) \), where
Now by considering the Lie algebra \( L \) as a Leibniz algebra and the map \( \mu \) as morphism of Leibniz algebras we may treat \((C^*(\mathbb{R}^3),L)\) as a Courant pair. It follows that we have extra cohomology classes in the second cohomology space \( H^2(L;A;L) \) of the Courant pair \((A,L)\) in comparison to the second cohomology space \( H^2_{\text{br}}(A,L;A) \) of the Leibniz pair \((A,L)\).

Recall that \( H^2(L;L) \) denotes the second cohomology space of \( L \) with coefficients in \( L \) (considering \( L \) as Leibniz algebra) and \( H^2(L;L) \) denotes the second cohomology space of \( L \) with coefficients in \( L \) (considering \( L \) as Lie algebra). Then the set \( \{[\phi],[\psi],[\phi],[\psi]\} \), where,

\[
\phi(e,e,\varepsilon)=e; \phi(e,e,\varepsilon)e=e; \phi(e,e,\varepsilon)e=0 \text{ for all } 1\leq i,j\leq 3, \phi(e,e,\varepsilon)=0,
\]

is a subset of a basis of \( H^2(L;L) \), but none of these representing cocycle contained in the Lie algebra cohomology space \( H^2(L;L) \). This computation is considered in the context of versal deformations of Leibniz algebras in.

Applying the coboundary map \( \delta \) in the deformation complex of Courant pair we have \( \delta (\phi)=\delta (\phi)=\delta (\phi)=0 \). Consequently \([0,0,\phi,0,0,\phi,0,0,\phi,0] \) generates elements in the cohomology space \( H^2(L;A;L) \). But none of these elements is in the Leibniz pair cohomology space \( H^2_{\text{br}}(A,L;A) \).

Define \((\alpha,\mu,\lambda)=(\alpha,\mu,\lambda)+i(0,0,\phi) \) for \( i=1,2,3 \). Then we can check that these are infinitesimal deformations of \((C^*(\mathbb{R}^3),L)\) which are also non-equivalent.

Moreover, these deformations are obtained only when we consider the Courant pair \((C^*(\mathbb{R}^3),L)\) as a Courant pair.

**Conclusions**

The deformation of a given structure characterize the local behaviour in the variety of a given type of objects. In order to study the deformation one needs a suitable notion of module or representation and then construct a deformation complex. In this work we develop a formal deformation of Courant pairs which includes the classical cases of Lie algebras and Leibniz pairs. Moreover, there are plenty of examples of the Courant pairs including the Leibniz algebras and Leibniz algebroids appear in algebra, geometry and in Mathematical physics. A Courant pair \((A,L)\) is a Leibniz pseudoalgebra over \((\mathbb{R},A)\) if \( L \) is also an \( A \)-module and the structure map is an \( A \)-module homomorphism such that following condition is satisfied: \([x,y;f]=f[x,y]+(\phi)(y)\) where \( x,y\in L \) and \( fA \). So it is also natural to expect a deformation theory for Leibniz-Rinehart algebroids by deducing the required deformation cohomology.

As in the classical cases of algebras over quadratic operads (e.g., Ass, Lie, Leib,...), one may look for a differential graded Lie algebra structure on the cohomology space of a Courant pair. Also, a Courant pair can be described as a non skew-symmetric version of OCHA and subsequently as an algebra over an operad. These questions are planned to be addressed in a separate discussion.
