Abstract

Sodium/glucose co-transporter 1 (SGLT1) is an active glucose transporter that takes up glucose into cells independent of the extracellular concentration of glucose. This transporter plays a critical role in maintaining glucose homeostasis at both physiological and pathological levels. The expression level of SGLT1 in normal and diseased human prostatic tissue has not been determined. We produced two rabbit polyclonal antibodies against human SGLT1, one each for immunohistochemical and Western blot analyses, and characterized the expression of SGLT1 in human prostate tissues: normal prostate (n=3), benign prostatic hyperplasia (BPH) (n=53), prostatic intraepithelial neoplasia (PIN) (n=9), and prostate cancer (PCa) (n=44). In normal prostate tissue, SGLT1 was weakly expressed exclusively in the epithelium. The transporter was significantly increased in the basal cells and stromal cells of BPH, increased in the epithelial cells of PIN, and frequently overexpressed in stromal cells and universally overexpressed in the tumor cells of PCa. The pattern of expression was shown as membranous/cytoplasmic staining in low-grade cancer cells and nuclear envelope staining in high-grade cancer cells. The SGLT1-positive stromal cells of BPH and PCa tissues were negative for tenascin, a marker of reactive stromal cells.

We concluded that SGLT1 is up-regulated in BPH and PCa, and SGLT1 may serve as a potential therapeutic target for treating these prostate disorders.

Keywords: SGLT1; Prostate; Prostate cancer; Benign prostatic hyperplasia

Introduction

Influx of glucose into cells is carried out by two main classes of glucose transporters, the facilitative glucose transporters (GLUTs) and the active sodium/glucose co-transporters (SGLTs) [1]. GLUTs mediate a concentration-dependent and energy-independent bidirectional process of glucose uptake. In contrast, SGLTs mediate an active Na+ gradient-dependent glucose uptake regardless of the extracellular glucose concentration [2,3]. The SGLT family consists of 3 members, SGLT1, SGLT2, and SGLT3 [1]; the last may function as a glucose sensor rather than a transporter [4].

Increased glucose uptake and GLUT expression are associated with pathological conditions, such as hypoxia, inflammation, and neoplasia. Hypoxia induces GLUT1 expression in neurons [5,6] and chondrocytes [6], and inflammation up-regulates GLUT1 in macrophages [7] and vascular endothelial cells [8]. GLUT1 is often induced in many cancers, including those of the breast, cervix, esophagus, lung, and liver [9]. Increased expressions of SGLT1 have been found in oral cancer [10], colorectal cancer [11], pancreatic cancer [12], and ovarian cancer [13].

Normal prostatic epithelium is not active in glucose metabolism [14]. However, glucose uptake has often been observed with high-grade prostate cancer (PCa) [15] hinting at an association between altered glucose metabolism and the pathogenesis of PCa. Yet several studies have found significantly decreased levels of GLUT expression in PCa [16,17]. The glucose transporter or transporters that are involved in the increased glucose uptake observed in PCa remain to be investigated.

To explore the possibility of a role for SGLT in pathogenesis of prostate diseases, we produced and characterized two rabbit polyclonal antibodies against human SGLT1 to examine its expression levels in human prostate tissues including normal, benign prostate hyperplasia (BPH), prostatic intraepithelial neoplasia (PIN), and PCa.

Materials and Methods

Antibody production and purification

Two peptides, CIETQVPEKKKGIFRR and CLRNSKEERIDLDAE, corresponding to amino acids 588-604 and 563-576 of human SGLT1 were used to raise rabbit polyclonal antibodies suitable for immunohistochemical analysis (SGLT1-IHC) and Western blotting (SGLT1-WB) respectively.

HTTrap affinity columns (General Electric, Upsalla, Sweden) were used to purify the SGLT1 antibodies from SGLT1 antiserum. To purify the antibody, the columns were coupled with the antigenic peptide at a concentration of 1 mg/mL in coupling buffer (0.2 M NaHCO3, 0.5 M NaCl, pH=8.3) for 30 minutes at room temperature. The column was then exposed to buffer A (0.5 M ethanolamine, 0.5 M NaCl, pH=8.3) and buffer B (0.1 M acetate, 0.5 M NaCl, pH=4) 3 times. Five hundred
microliters of the pre-immune serum and 500 µL of the antiserum were diluted in binding buffer (0.2 M NaH₂PO₄, pH=7.0) and passed through the column. The bound antibodies were eluted with 3 mL of elution buffer (1 M glycine-HCl, pH=2.7). The eluant was immediately neutralized with neutralizing buffer (1 M Tris-HCl, pH=9.0), and 0.02% Na₂S₂O₃ was added to the purified antibody for long-term storage.

**Cell culture**

PC3, PC3-MM2, LNCaP, HCT116, and HEK293T were from our laboratory cell stocks. All types of cells were cultured in Dulbecco’s modified Eagle’s medium (Invitrogen, Carlsbad, CA) and supplemented with 5.5 mM glucose, 10% fetal bovine serum, and 1% penicillin/streptomycin. Cells were cultured at 37°C with 5% CO₂.

**Plasmid construction**

Human SGLT1 cDNA was amplified from a cDNA library using a pair of primers, GCTGCCCACTTGGAAGTACG and CAGCAAAAAGGTAGGACTTCAGG, corresponding to the 5’ and 3’ UTR of SGLT1. A second round of polymerase chain reaction was performed using a pair of nested primers, TAGTCTGCAGGCGAAATATGCTAGGCCAAAGACACCGACAGCCGTTAC and ATAGAATTCATGGAAGTACGACCCCTGAGCCCAAGACCAA. The polymerase chain reaction product of SGLT1 was cloned into a PXXF2 expression vector between the SalI and EcoRI sites, which produced a SGLT1 cDNA with a FLAG tag at both the N-terminus and the C-terminus. The construct was confirmed by sequencing. The tagging at both ends allows the protein to be expressed at a stable level in the absence of epidermal growth factor receptor (EGFR) and was used as a positive control for antibody characterization.

The U6 promoter-driven small interfering (shRNA) vector with green fluorescent protein (GFP) expression (pRNA-U6.1/Neo; GenScript) was used to express shRNA against SGLT1. The target sequence for SGLT1 shRNA was TCTTCCGCATCCAGGTCAAT. The negative control shRNA sequence was GAACAATGTTGACCAGGTGA.

**shRNA knockdown, RT-PCR and western blotting**

Whole-cell lysates of intact cells were transfected with vectors expressing FLAG-tagged SGLT1 in combination with vectors expressing SGLT1 shRNA or its corresponding scrambled control. At the time of transfection, cells were cultured in their respective media without the supplemented 1% penicillin/streptomycin. Six hours post-transfection, the media were replaced with normally formulated media. At 48 hours after transfection, one set of cells was used for RNA isolation and RT-PCR determination of SGLT1 mRNA (primers are: 5'-TGGCAAGGGCAAGTGA-3' and 5'-ATGATATGTCGGCCCGAAGA-3') for the RT-PCR reaction program was set to 50°C for 1 hr and 94°C for 5 min, followed by 30 cycles of 94°C for 40 s, 56°C for 40 s, and 72°C for 50 s with an extension at 72°C for 10 min. The PCR products were analyzed with a 1% agarose gel stained with ethidium bromide and visualized under ultraviolet light. Another set of cells were lysed for 30 minutes on ice in RIPA buffer (Sigma Aldrich, St. Louis, MO) supplemented with protease and phosphatase inhibitors for Western Blot and immunoprecipitation assays. The concentrations of the protein samples were measured using a Qubit fluorometer (Invitrogen), and equal amounts of protein samples were loaded onto a 10% SDS-PAGE gel and transferred to a polyvinylidene difluoride membrane. Membranes were incubated in 5% milk to block the non-specific binding sites for 30 minutes and then in optimized concentrations of SGLT1-WB or primary anti-FLAG antibody (Santa Cruz Biotechnology, Santa Cruz, California) at 4°C overnight. After being washed with 3x phosphate-buffered saline (PBS), membranes were incubated with horseradish peroxidase-conjugated secondary antibodies (Santa Cruz Biotechnology) at 1:3000 dilutions for 1 hour at room temperature. Luminescent signals were detected using an enhanced luminescence kit (Pierce ThermoScientific, Rockford, IL) and exposed to X-ray film (VWR, Bridgeport, NJ).

**Immunoprecipitation**

HEK 293 cells were transfected with double flagged SGLT1. After 24 hours of post transfection cells were washed in 1X phosphate buffered solution and lysed with RIPA buffer (50 mM Tris-HCl, pH 8.0, with 150 mM sodium chloride, 1.0% Igepal CA-630 (NP-40), 0.5% sodium deoxycholate, and 0.1% sodium dodecyl sulfate), supplemented with protease inhibitors cocktail, for 6 hours at 4°C on a shaker. The cell lysates were then centrifuged for 2 minutes at 12000 rpm and 500 µgs of supernatants were incubated with 25 µl of sepharose protein A/G beads (Santa Cruz Biotechnology, Santa Cruz, CA, USA) conjugated with 500 ng anti-flag antibody (Sigma) for overnight. Samples were then centrifuged and washed with RIPA buffer three times before boiled in Laemmle buffer (Biorad, Hercules, CA, USA) and subjected to Western blot analysis using the SGLT1-WB antibody.

**shRNA knockdown and immunocytochemical analysis**

Vectors expressing SGLT shRNA or its corresponding scrambled control were transiently transfected into HCT116 cells cultured on collagen-coated glass coverslips using Lipofectamine 2000 (Invitrogen) in Opti-MEM (Invitrogen). At the time of transfection, cells were cultured in their respective media without the supplemented 1% penicillin/streptomycin. Six hours post-transfection, the media were replaced with normally formulated media. At 30 hours post-transfection, the cells were fixed with 4% paraformaldehyde and permeabilized with 0.5% Triton X-100 (Sigma-Aldrich) in PBS.

Slides were blocked by incubating cells in normal goat serum for 1 hour followed by primary antibody against SGLT1 (1:200 in PBS) overnight at 4°C. After being washed, cells were exposed to Alexa Fluor 594 secondary antibody (1:200; Invitrogen) for 1 hour at room temperature. After three washes with PBS, coverslips were mounted on microscopic slides using 10 µl of VECTASHIELD mounting medium with 4',6-diamidino-2-phenylindole (DAPI) (Vector Laboratories, Burlingame, CA). Fluorescence images were captured and analyzed with a fluorescent Olympus microscope.

**Tissue preparation**

Paraffin-embedded tissue microarrays containing normal human tissues and human prostate tissues, BPH tissues, PIN tissues, and PCA tissues were purchased from Lifespan Biosciences (Seattle, WA). An additional five BPH tissue samples were obtained from the Methodist Hospital Research Institute’s Department of Urology (Houston, TX) tissue bank under the approval of its institutional review board.

**IHC analysis**

**Immunoperoxidase staining**

For immunoperoxidase staining with diaminobenzidine labeling, tissue sections were dewaxed in xylene and rehydrated in a graded series of alcohol and PBS. Antigen retrieval was performed using heated citrate buffer. Endogenous peroxidase activity was blocked with 3% hydrogen perofoxide in
methanol. Samples were incubated in a blocking solution (5% donkey serum in PBS) for 1 hour at room temperature and then overnight at 4°C with the primary antibody against SGLT1 diluted in the blocking solution (1:200). After three washes in PBS, samples were incubated with a biotinylated goat anti-rabbit secondary antibody (1:500) for 1 hour at room temperature and then washed thoroughly. An ABC staining kit was used for chromogenesis. Slides were then briefly counterstained with hematoxylin and mounted.

**Immunofluorescent co-staining:** For immunofluorescent co-staining of SGLT1 and tenascin, tissue slides were co-incubated with the rabbit polyclonal antibody against SGLT1 (1:200 dilution) and a monoclonal anti-tenascin antibody (1:200) in PBS containing 10% donkey serum. After being washed three times with PBS, tissues were incubated with Alexa Fluor 488–conjugated donkey anti-rabbit immunoglobulin G, Alexa Flour 594–conjugated donkey anti-mouse immunoglobulin G, or both (Invitrogen) in PBS containing 10% donkey serum for 30 minutes at room temperature. The stained samples were then washed three times (5 minutes per wash) with PBS, also at room temperature. Fluorescence images were captured and analyzed with a confocal microscope (Olympus).

**Results**

**Characterization of rabbit antibodies against human SGLT1**

**SGLT1-WB**: The specificity of SGLT1-WB was characterized by the following experiments. First, we transiently transfected FLAG-tagged SGLT1 plasmids with either SGLT1 shRNA or control shRNA into HEK293T cells and determined the levels of FLAG-tagged SGLT1 of these cells by Western blotting using a primary antibody against FLAG. The tagged SGLT1 produced four major bands of >250, 150, 80, and 55 kDa, which were all substantially reduced only by the SGLT1 shRNA in a dose-dependent manner (Figure 1A). The >250 kDa and 150 kDa bands might be aggregates of overexpressed SGLT1. Because the exogenous SGLT1 was flagged at both the N- and C-termini, the expected molecular weight was 80 kDa. The 55 kDa band is likely degraded SGLT1. Using the same set of cell lysates, we detected the expression of SGLT1 shRNA in these cells using the SGLT1-WB antibody, which was consistent with the changes of SGLT1 mRNA levels determined by RT-PCR (B). Actin was used as internal controls.

**SGLT1-IHC**: Characterization of rabbit antibodies against human SGLT1 by immunohistochemical analysis of cells transfected with control shRNA or SGLT1 shRNA using SGLT1-IHC. Cells containing shRNA appear green (arrows) due to the expression of GFP under the control of an autonomous promoter and the SGLT1 signal is red. Nuclei are stained blue with DAPI. The specificity of SGLT1-WB was characterized by immunohistochemical analysis of a human normal intestine sample using SGLT1-IHC with or without blocking peptides (1 mg/mL).

**Figure 1**: Characterization of the SGLT1-WB antibody by Western blot analysis. Detection of FLAG-tagged SGLT1 transiently transfected into HEK293T cells in combination with control shRNA or SGLT1 shRNA, using A, an anti-FLAG primary antibody or B, SGLT1-WB. C, WB detection of immunoprecipitated flagged SGLT1 expressed in HEK293 cells using the SGLT1-WB antibody. D, SGLT1 expression in PC3, PC3-MM2, and LNCaP cells. E, Detection of endogenous SGLT1 of PC3 cells transfected with control shRNA or SGLT1 shRNA, using SGLT1-WB. Actin was used as the loading control.

**Figure 2**: Characterization of the SGLT1-IHC antibody using HCT116 human colon cancer cells. A, Western blot analysis of endogenous SGLT1 in cells transfected with control shRNA or SGLT1 shRNA using the SGLT1-WB antibody, which was consistent with the changes of SGLT1 mRNA levels determined by RT-PCR. B, Actin was used as internal controls. C, Immunocytochemical analysis of cells transfected with control shRNA or SGLT1 shRNA using SGLT1-IHC. Cells containing shRNA appear green (arrows) due to the expression of GFP under the control of an autonomous promoter and the SGLT1 signal is red. Nuclei are stained blue with DAPI. D, Immunohistochemical analysis of a human normal intestine sample using SGLT1-IHC with or without blocking peptides (1 mg/mL).
SGLT1-WB reduced by SGLT1 shRNA in a dose-dependent manner (Figure 1B). To further determine the specificity of the SGLT1-WB antibody, we performed an assay of immunoprecipitation coupled with Western blot (IP-WB) using the anti-flag antibody for IP and the SGLT1-WB for WB, and an irrelevant rabbit IgG as a negative control. As shown in Figure 1C, the immunoprecipitated flagged SGLT1 was detected by the SGLT1-WB antibody. We then determined the expression of endogenous SGLT1 in a panel of cell lines PC3, PC3-MM2, and LNCaP. SGLT1-WB detected a single band at the expected 75 kDa (endogenous SGLT1) in the PC3, PC3-MM2, and LNCaP lines (Figure 1D). To determine the specificity of the endogenous SGLT1 signal, we transiently transfected SGLT1 shRNA and its control shRNA into PC3 cells and determined the expression levels of the endogenous SGLT1 using SGLT1-WB. The SGLT1 signal was reduced by the addition of SGLT1 shRNA (Figure 1E). Taken together, these data suggest that SGLT1-WB is suitable for Western blot analysis.

SGLT1-IHC: To characterize the SGLT1-IHC antibody, we conducted two types of control experiments. First, we tested the specificity of this antibody by using immunocytochemical analysis on cells treated with control shRNA or SGLT1 shRNA. Because colon cancers express SGLT1 (11) we used colon cancer HCT116 cells as a positive control. The expression of SGLT1 in HCT116 cells treated with control shRNA or SGLT1 shRNA was first confirmed by Western blotting using the SGLT1-WB antibody (Figure 2A) and RT-PCR analysis of the SGLT1 mRNA (Figure 2B). Then we performed immunocytochemical staining using SGLT1-IHC with HCT116 cells. The shRNA expression vector expresses green fluorescent protein (GFP) under an autonomous CMV promoter—that is, cells that have taken up the shRNA vector are GFP-positive, which allows us to distinguish shRNA-transfected cells from non-transfected cells. We used Alexa Fluor 594–conjugated secondary antibody to label the SGLT1-IHC signal. The control shRNA transfected and non-transfected cells presented equal levels of SGLT1; however, the SGLT1 signal was significantly reduced in the SGLT1 shRNA–transfected cells compared with the control shRNA–transfected and non-transfected cells (Figure 2C). To further characterize SGLT1-IHC, we compared the immunohistochemical signals produced by SGLT1-IHC in the absence or presence of its blocking peptides in normal human intestine tissue, which is known to express SGLT1 [18] and a SGLT1 negative tissue, the brain [19]. SGLT1-IHC gave rise to clear positive signals in the epithelial cells of the small intestine, which were significantly reduced by its blocking peptides, and the brain tissue was completely negative.

Figure 3: Expression of SGLT1 in normal and BPH prostate tissues. Immunohistochemical stained SGLT1-positive cells appear brown. Right panel is magnification of boxed area in left panel. A, Normal prostate. B-D, BPH tissues. Arrows point to basal cells, arrowheads indicate stromal cells. Bar=50 µm.

Figure 4: Expression of SGLT1 in PIN tissue. A-D, SGLT1-positive cells appear brown. Right panels are magnification of boxed areas in left panels. Bar=50 µm.
SGLT1 up-regulation in diseased human prostatic tissue: Using SGLT1-IHC, we profiled the expression of SGLT1 in samples of normal prostate (n=3), BPH (n=53), PIN (n=9), and PCa (n=44). SGLT1 was weakly expressed in the luminal epithelial cells of normal tissue (Figure 2D). All the BPH tissues had a discontinuous layer of basal cells with high levels of SGLT1 expression as well as SGLT1-positive stromal cells (Figure 3). Even greater SGLT1 expression was consistently observed in the epithelial cells of PIN samples (Figure 4). Cancer cells of all the prostate cancer samples were strongly positive for SGLT1 (Figure 5). Overall, the examples exhibited a pattern of membranous or cytoplasmic staining in cells of lower grade cancers and nuclear envelope staining in cells of high-grade cancers. SGLT1-positive stromal cells were also observed in PIN and PCa tissues but to a lesser extent than in the BPH samples. A semiquantitative summary of SGLT1 expression in these prostatic tissues is presented in Table 1.

SGLT1-positive, tenascin-negative stromal cells in diseased human prostatic tissue: Tissue stromal cells can be activated by pathological insults, which is often the case for diseased prostates [20,21]. Because we observed that stromal cells of BPH tissues and some PCa tissues were positive for SGLT1, we performed immunofluorescent co-staining of SGLT1 with a reactive stromal cell marker, tenascin [21], to determine whether the SGLT1-positive stromal cells were reactive stromal cells. To our surprise, the SGLT1-positive stromal cells were tenascin negative (Figure 6), suggesting they are not reactive stromal cells in BPH or PCa tissue.

Discussion

The normal human prostate gland produces, accumulates, and secretes high levels of citrate, which is predominantly derived from the oxidation of fatty acids [22]. Because the normal prostate is not active in glucose metabolism but relies on fatty acid metabolism, the role of glucose and its transporters in prostate biology has not been adequately investigated. However, emerging data suggest that both BPH and PCa are associated with altered glucose metabolism. Blood glucose levels positively correlate with prostate size in BPH [23] and the incidence of both BPH and PCa correlates with metabolic syndrome [24] of which glucose intolerance is one of the major abnormalities. In addition, high-grade PCa and PCa metastases exhibit increased glucose uptake [15,25]. Moreover, PCa cells are sensitive to glucose starvation—
induced autophagy [26]. The cumulative evidence strongly suggests that glucose metabolism is critically involved in the pathogenesis of prostate diseases, such as BPH and PCa.

Our study shows that the expression of SGLT1 is significantly increased in basal cells and stromal cells of BPH tissue compared with normal prostate tissue. The heterogeneous expression of SGLT1 in the basal cells and stromal cells of BPH is intriguing, which suggests that neither cell type is metabolically homogenous. These results strongly suggest a one-way glucose flux from the basal cells to the luminal epithelial cells in the normal prostate. The biological roles of SGLT1-positive basal cells and stromal cells in the pathogenesis of BPH demand further study.

The highly increased expression of SGLT1 in the epithelial cells of PIN and PCa cells relative to the cells of normal prostate and BPH tissues suggests that a high level of glucose is required during the pathogenesis of PCa. GLUT1 has been found to be expressed exclusively in luminal epithelial cells and in borders between the basal and luminal epithelial cells [17] and GLUT1 expression is decreased in PCa cells compared with non-cancer cells [16,17]. This shift from GLUT1 to SGLT1 in epithelial cells indicates a higher demand for glucose during the pathogenesis of PCa.

The stroma of PCa tissues also contains regions with a variable amount of SGLT1-positive stromal cells; these cells are not tenascin-

*The semi-quantification was carried out by two individuals in a blinded manner using the same normal prostate tissue as a standard reference. The signal density of normal prostate epithelial cells is considered as “++;” and the signal density of the basal cells of BPH is considered as “++-”.

**SGLT1-positive cells and total stromal cells were counted from 3 random selected areas under 200x magnification, and the percentage of SGLT1-positive cells is calculated by the number of SGLT1-positive cells/total stromal cells. The values are presented as mean ± SD.

The stroma of PCa tissues also contains regions with a variable amount of SGLT1-positive stromal cells; these cells are not tenascin-positive reactive stromal cells [27]. Reactive stromal cells have been shown to play critical roles in the pathogenesis of BPH and PCa [20,28]. These data added another layer of complexity to our increasing understanding of the role of stromal cells in the development of PCa and BPH. The variability of SGLT1-positive stroma in PCa might contribute to the lack of consistency between 18F-fluoro-2-deoxy-2-D-glucose (FDG) positron emission tomography results of early-stage PCa [29] when tumor foci are small and scattered, because the FDG uptake by SGLT1-positive stromal cells may overshadow the uptake by cancer foci. The translocation of SGLT1 into the nuclear envelope of high-grade PCs that we observed is also intriguing and is reminiscent of proteins such as pyruvate kinase M2 [30] protein kinase C η [31] CXCR4 [32] annexin A1 [33] and EGFR [34] that reside in the non-nuclear compartments of normal stromal and translocate to the nucleus of cancer cells, where they are involved in nuclear events critical for cancer cell proliferation and survival.

The overall expression pattern of SGLT1 in normal prostate, BPH, and PCa tissues is very similar to the expression pattern of EGFR, which is weakly expressed in the epithelial cells of normal prostate tissue, moderately expressed in the stromal cells in BPH, and significantly increased in cancer cells [35-38]. These findings suggest that SGLT1 and EGFR expression might be regulated under a common mechanism, and they support our previous finding that EGFR interacts with or stabilizes SGLT1 in PCa cells [39]. Further investigation is needed to understand the association between EGFR and SGLT1 during the development of PCa.
