Abstract

A national survey to obtain information about the Quality Assurance (QA) procedures and methods being followed at Indian radiotherapy centers for intensity modulated radiation therapy (IMRT) was conducted. A questionnaire containing parameters relevant to IMRT QA was evolved to collect the information pertaining to the QA of IMRT delivery system, QA of IMRT treatment planning system, and patient specific IMRT QA. The questionnaire was circulated to 40 hospitals in the country and responses of 31 centers were received. Survey results showed that 71% centers are having adequate machine specific IMRT QA programme, 19% centers have inadequate machine specific IMRT QA programme and 9% centers have irrelevant machine specific IMRT QA programme. No specific answer for question of QA tests of TPS specific to IMRT were received from the user. Almost all the centers have programme of setup verification of the patient by means of EPID/DRR/OBI. However, 91% of centers could not provide any information about the QA methodology of the devices used for setup verification. For patient specific dosimetric QA, almost all the hospitals have the program of pre-treatment dose verification using calibrated ionization chambers of sensitive volumes in the range of 0.01 to 0.65 cc. Dosimetric verification is performed by combining dose from all gantry angles to a single gantry angle. Two dimensional (2D) dosimetry systems such as radiographic and radiochromic film, 2D array of ionization chambers/ semiconductor diodes and EPID are also used in patient specific dosimetry verifications. Majority of the centers (about 48%) accept the plan with 3% dose difference and 3 mm dose to distance agreement criteria with gamma index less than unity. However, a number of other acceptance criteria specific to institution and tumor site are being also followed. This survey reveals that a variety of IMRT QA program is being followed at the Indian hospitals. This study has brought into focus the need to evolve a national protocol for IMRT QA so that treatment outcomes of all the IMRT centers of country can be compared.

Keywords: IMRT QA; Survey; Patient dosimetry; Dose verification; QA protocol

Introduction

Intensity modulated radiation therapy (IMRT) is a complex radiotherapy techniques which allows to deliver radiation dose conforming to complex shaped target volumes and at the same time efficiently spare the surrounding normal/healthy structure. Thus it is the treatment of choice for curative radiotherapy. There are about 280 radiotherapy centre in India out of which about 60 are practicing IMRT. The implementation of IMRT in Indian Hospital is increasing at the rapid rate and in the future more number of centers will be practicing this technique. The IMRT involves a high risk of mistreatment due to its nature of sharp dose gradient at the boundary, complicated treatment planning and delivery procedure. Any small geometrical miss in patient setup as well as in mechanical accuracy of beam delivery can lead to a large deviation of delivered dose from the planned one. Since high geometric and dosimetric accuracy is required for this advanced technique, verification of the delivery of IMRT [Intensity Modulated Radiation Therapy Collaborative Working Group, 2001] dose distributions is a prerequisite for its safe and efficient application(Saarilahia et al., 2005).

The successful use of IMRT technique is lying with implementation of comprehensive QA programme before and during the IMRT in routine clinical practice. Since starting of the IMRT for clinical practice a number of reports and chapters in a book have been published (Intensity Modulated Radiation Therapy Collaborative Working Group, 2001; Ezzell et al., 2003; Galvin et al., 2004; Bortfeld, et al., 2006; Palta and Mackie, 2003). All these reports emphasize the importance of performing a comprehensive acceptance testing, commissioning and QA programme of IMRT equipment.

The need for these types of verification programmes has been demonstrated, during an independent dose evaluation performed by the Radiological Physics Centre (RPC) of institutions wishing to participate in a Radiation Therapy Oncology Group (RTOG) IMRT protocol (Molineu et al., 2005; Ibbott, 2006). Roughly one third of surveyed hospitals fail to meet the acceptance criteria set by RPC. These results clearly demonstrate that institutions vary significantly in their ability to deliver dose distributions that agree with their own treatment plans, and that quality assurance tests play a critical role in IMRT planning and delivery. There is, however, not yet consensus to what extent tests, dealing with issues specific for IMRT, should be performed (Ezzell et al., 2003; Palta and Mackie, 2003; Ahnesjo, et al., 2006; ICRU Report, 2010). IMRT requires verification of a number of parameters related to planning as well as delivery system which is still an ad hoc process at majority of the centers. This is because new systems are continuously becoming available, while also there exist no clear guidelines and criteria for the accuracy required. Furthermore, the variation in complexity and clinical practice of IMRT...

in different centers make it unlikely that a single QA programme would fit the needs for all radiotherapy departments. Many centers have developed their own QA procedures for IMRT, and only recently some more specific suggestions for tolerance limits and action levels for planning and delivery of IMRT have been provided (Palta and Mackie 2003; Stock, et al., 2005; McDermott, et al., 2007; Sanchez-Doblado, et al., 2007).

In another survey (Mijnheer, et al., 2004; Gillis, et al., 2005) it has been demonstrated that each institution applies its own quality assurance (QA) methods. Thus complicating inter-comparisons between institutions. Each user of IMRT has liberty of using any recommendation/methodology to fulfill QA requirements of IMRT. In India, physicists involve in the practice of IMRT and other complex techniques are not having any common protocol or procedure to carry out QA program. Quicker and precise QA methods are preferred in radiotherapy departments considering large patient loads. However there is a need to evolve a national protocol in IMRT so that treatment outcomes of all the IMRT centre of country can be compared. Before evolving such a protocol it is equally important to know the existing procedure of QA in IMRT used at these centers. Keeping this in mind, a national survey on QA procedure/methods was conducted. This paper describes the results of IMRT QA survey which aim to understand the current QA methodologies, refining them to be as intuitive, efficient, and meaningful as possible; Evolved a unified IMRT QA protocol, based on socio-economic status, experience and relevant clinical end points for Indian scenario.

Materials and Methods

A questionnaire containing parameters relevant to IMRT QA was evolved to collect the information about the exact practice of IMRT QA being followed at the hospitals. As the aim of this survey was to understand and extract the information about the QA methods being used by the hospitals, emphasis was given on descriptive answer over multiple choice type answers. Table 1 show the IMRT QA questionnaire which was evolved for conducting the survey. The questionnaire contains three major part of IMRT QA namely, (i) QA for IMRT delivery system, (ii) QA for IMRT treatment planning system (IMRT-TPS), and (iii) patient specific IMRT QA. Under QA for delivery system, information about detailed machine specific QA which includes details of the machine parameters that are evaluated in the IMRT equipped medical linac and methods and tools for testing these parameters have been included. In the QA for IMRT-TPS, description about the procedure adopted for QA of dosimetric and non-dosimetric parameters used for IMRT planning and their test methods were enquired. Though the section on patient specific QA was further divided: (a) QA for setup verification, and (b) QA specific to the dosimetric methods. But, importance was given to extracting information related to methodologies followed for the dosimetric verification.

Table 1: Format of IMRT QA survey questionnaire which was circulated to radiotherapy centres in India.
Information about the make and model of MLC which is used for delivering the IMRT was asked to understand suitable QA methodology related to MLC. Considering the importance of imaging in IMRT, imaging modalities used for IMRT planning in the hospitals were also explored. Question related to acceptance criteria of an IMRT plan for treatment after the pre-treatment dose verification was also included. Information regarding site as well as centre specific IMRT planning such as margin for PTV and acceptance criteria was enquired. It was also enquired whether user has detected any deviation larger than acceptable tolerance during their QA so far. The survey was sent to 40 IMRT practicing hospitals.

Analysis of the machine specific QA were done by scrutiny of the data received from different hospitals. This scrutiny was done by dividing the hospitals in three categories: (a) Centers with Adequate Machine specific IMRT QA program - those hospitals which have programme of machine specific QA relevant to IMRT following standard recommendations/protocols (b) Centers with Inadequate Machine specific IMRT QA program - if the information provided by the hospitals were not sufficient, and (c) Centers with Irrelevant Machine specific IMRT QA program.

Results and Discussion

Out of 40 radiotherapy centers in India practicing IMRT, 31 centers responded to this survey. Figure 1 shows the pie chart of the information provided by the hospitals related to machine specific QA for IMRT. It can be observed from this chart that 71% centers are having adequate machine specific IMRT QA programme, 19% centers have inadequate machine specific IMRT QA programme and 9% centers have irrelevant machine specific IMRT QA programme. The 9% centers have described QA program relevant to a conventional medical electron linear accelerator with some arbitrary test methods. Regarding the question of QA tests of TPS specific to IMRT, a variety of answer were received from the hospitals. Almost all the hospitals have a different answer for this question. Some of the users have described a few QA tests for TPS listed in IAEA TRS 430 (IAEA Technical Series Report 430, 2004) and some of them refer AAPM Report 62 (Benedick, et al., 1998). As is known to all, neither TRS 430 nor AAPM Series Report 430, 2004) and some of them refer AAPM Report 62 described a few QA tests for TPS listed in IAEA TRS 430 (IAEA Technical Series Report 430, 2004) and some of them refer AAPM Report 62 (Benedick, et al., 1998).

Figure 2: Bar diagram of the acceptance criteria of IMRT plans followed by the hospitals for pre-treatment dose verification: A: 5% dose difference and 3 mm DTA; B: 3% dose difference and 3mm DTA ; C: 3% dose difference and 3mm DTA (Large field); 2% dose difference and 2mm DTA (Small field); D: 4% dose difference and 3mm DTA (Low dose low gradient); E: 3% dose difference and 3mm DTA (High dose low gradient) 3- 5% dose difference and 4mm DTA (Low dose high gradient); E: 2% dose difference and 2 mm DTA ; F: 3% dose difference and 3 mm DTA/ 5% dose difference and 5 mm DTA (in some specific cases); G: inadequate information.

that erroneous measurement techniques are the reasons of this deviation more than acceptable limits. These centers have indicated thus far. However, about 33% users reported that they have observed deviation more than acceptable limit during their dosimetric QA planning.

of 0.6 cm in head and neck and up to 1.5 cm in pelvic region of IMRT region during IMRT planning. Very few centers reported PTV margin in head and neck cases and 0.5 - 1.0 cm PTV margin in the pelvic region. A few centers also provided the information for PTV margins in some cases only. A Volume (PTV) in various cancer cases, majority of centers responded development in this direction.

to deal with all types of treatment sites will be a very important step. It should also be initiated to ensure safety and efficacy of this treatment outcomes.

Considering the wide variety of cancer cases treated by IMRT in India, complex site for the IMRT, are also treated at Indian hospitals. However, breast as well as lung cases, which are considered most preferred site for IMRT in India. It can be observed from this survey that head and neck and pelvic region cases are most preferred site for IMRT in India. Thus, a variety of IMRT QA program in totality is being followed at Indian hospitals. There is a need to evolve a national protocol for planning system and delivery system involved in the IMRT along with conventional treatment machines. On the basis of this survey we are working to evolve a exclusive common QA programme for planning system and delivery system involved in the IMRT along with patient specific IMRT QA. This common QA programme can be adopted by all the IMRT practicing centers in the country.

Conclusions

A national survey on IMRT QA by means of a properly designed questionnaire was carried out at 40 radiotherapy centers in India. The survey reveals that majority of Indian hospitals have adequate machine specific IMRT QA programme but highly inadequate QA programme for the treatment planning systems. Pre-treatment dose verification is carried out at almost all the centers but measurement techniques and plan acceptance criteria are institution specific. Thus, a variety of IMRT QA program in totality is being followed at the Indian hospitals. There is a need to evolve a national protocol for IMRT QA so that treatment outcomes of all the IMRT centers of country can be compared.
